The second institution to be considered is the Bahir Dar University located some 575 km from the capital city—Addis Ababa. Bahir Dar University was established in 1993 by combining the old Polytechnic Institute, which was established in 1963 under the cooperation between the government of the Soviet Union and the Imperial government of Ethiopia, with the Bahir Dar Academy of Pedagogy, which was established in 1972 by a cooperative agreement and contribution made by the Ethiopian government and UNESCO/UNDP. Thus, the current library houses the collections of both institutions. The University Library system has five libraries: the main library, the Law Library, Freshman Library, the Engineering Library that is located in the Engineering Faculty campus, and the Textile Industry Institution Library. The collection of the libraries has about 86,000 printed books.^[16]

The third institution to examine is Haramaya University and its libraries which is located 510 km east of the capital in the town of Haramaya. Haramaya University was established in 1952, and was formerly known as the Imperial Ethiopian College of Agriculture and Mechanical Arts which then became Alemaya University of Agriculture (1985). It was founded by an agreement made by the then government of Ethiopia and the United States of America, and at the beginning, the Oklahoma State University was given the responsibility for finding staff from abroad and for running the academic research and extension programs. The college was also responsible for coordinating

the agricultural research and extension programs in the country. The library system of the university has four branches: the main library, the School of Graduate Studies Library, and the Female Students' Library are located in the main campus in the town of Haramaya, whereas the Health Sciences Library, which was opened in 2003, is situated in the city of Harar. The collection in the main campus consists of 140,350 items that cover a wide range of academic subjects currently offered by the university.^[17]

The last university library to be considered is the Jimma University Library. Jimma University is located about 335 km southwest of the capital. It was established in 1999 by merging the former Jimma College of Agriculture, which was founded in 1952, and Jimma Institute of Health Sciences, which was founded in 1983.

The university library system was created in 1985 to promote the instructional, research, and public service goals of the university community through the acquisition of necessary materials. The University Library has seven branches, each specializing in a particular subject area: Health Science Library, Education Library, Technology Libraries, Social Science Library, Law Library, Graduate Studies Library, and College of Agriculture Library. The total collection is about 131,715 items which includes books, monographs, texts, journals, magazines, and databases. It also offers full text electronic databases and audiovisual materials.

School Libraries

In IFLA's 2007 World Report,^[18] the government of Ethiopia did not provide the number of school libraries found in the country. During the time of Emperor Menelik II, the first high school Teferi Makonnen was opened in 1908 in Addis Ababa. In the 1960s and 1970s, the Ministry of Education made a concerted effort to improve library services in schools with the help of a UNESCO expert who came to study and make recommendations on the development of various kinds of libraries for Ethiopia.

Efforts were made to improve the library services in high schools in the 1960s and 1970s. The Ministry of Education started to train school librarians and to purchase books following the recommendations of the UNESCO expert Paton (1964).^[18] However, school libraries still have a shortage of books and trained manpower.

Special Libraries

In Ethiopia, there were about 100 special libraries which are affiliated with the various ministries and governmental departments, research centers or institutes, and international organizations in the 1990s.^[19] The majority of the special government libraries are located in the ministries and parastatal organizations and serve the various professionals working for them. Examples of these include the

governmental libraries of the Ministry of Agriculture and Commission for Water in Addis Ababa, and parastatal libraries, such as those of the Ethiopian Institute of Agricultural Research (EIAR) and the Medical Research Library of Ethiopia.^[19] Here below, we will discuss the EIAR Library and Documentation Center, the Ethiopian Orthodox Library–Museum, and the Ministry of Foreign Affairs Library.

The EIAR Library and Documentation Center is located in Addis Ababa. It was established in 1966.^[19] The EIAR Library and Document Center's collection includes a variety of materials on agriculture. It has print, electronic resources, and CD-ROMs, such as books and journals for the staff of the research center, postgraduate students, and other research and development workers from other institutions.^[20]

The Ethiopian Orthodox Library–Museum was inaugurated on July 13, 2004 in Addis Ababa. The objectives of the library–museum are to preserve books and other historical relics for the coming generation and to assist local and international scholars in carrying out research on the Ethiopian Orthodox Church.

The Ministry of Foreign Affairs has its own library located in the premises of the ministry. The collection of the library is mainly used by the staff members of the ministry. The library houses international documents on political, social, and economic conditions of the country and other countries around the world. The library receives free publications locally from different publishers as well as from international organizations abroad.

Among the major international special libraries found in Ethiopia, the UN Economic Commission for Africa's (ECA) library and the library for the International Livestock Research Institute (ILRI) will be considered.

The ECA library was opened in 1959 to cater to the administrative and information needs of the commission and its member states. The collection of the library includes African government documents, periodicals, pamphlets, maps, microfiches, CD-ROMs, videotapes, books on Africa, bibliographic databases, and online databases.

ILRI, a nonprofit organization, was established in 1994 by merging the former International Livestock Center for Africa founded in 1974 and International Laboratory for Animal Diseases created in 1973. The headquarters of the institute is in Nairobi, Kenya with a principal campus in Addis Ababa. The organization focuses on issues around livestock management in poor countries. The library (information center) in Addis was launched in the 1980s.^[19] It has a diverse collection of books, journals, and CD-ROMs in print and online forms, as well as microfiche, videotapes, journals, theses, conference proceedings, maps, photographs, newspapers, and other forms of literature. The library also houses a unique microfiche collection of 30,000 unpublished documents from research centers in over 25 countries of sub-Saharan Africa.

Other special libraries that provide invaluable service to the community are the British Council, Alliance Française, and the German and Italian Cultural Institutes.

Library Education

As indicated earlier, one of the responsibilities of the National Library of Ethiopia has been to organize formal professional training to allow the trainees to acquire proper knowledge of the profession and its practices.^[19] To this effect, the formal organized professional training in the library profession started in 1959^[7] with a few short courses organized by the Ministry of Education in the evenings. The instructors came from the United States of America, the National Library itself, the United Nations Economic Commission for Africa Library, and the University College of Addis Ababa. To further strengthen the profession, the first Ethiopian graduate student was sponsored to obtain a higher degree in librarianship in the United States in the 1960s.

In 1966, the Haile Selassie I University introduced librarianship courses as a UNESCO teacher-training project.^[21] The main objective of this project was to produce librarians who would be working in small school libraries.^[8] In addition, the university began to offer 1-year full-time and 2-year part-time library science courses in order to produce mid-level librarians. More people were sent abroad for training in the library profession, and those started to return in the 1970s. Moreover, a new Bachelors degree program in Library Science was introduced in 1988. Finally, with the assistance of the International Development Research Center (IDRC) and UNESCO, a new program leading to a masters degree in information science began with the establishment of the School of Information Science (SISA) at AAU (formerly known as Haile Selassie I University) in 1989. Unfortunately, the training of librarians in undergraduate degree and diploma programs has ceased in the university since 1994 and some activities have been undertaken in private colleges to fill this gap. Thus, the dearth of mid-level library professionals still prevails in the country.

Professional Association

Another important item that needs to be addressed for the development of the library profession is the existence of some kind of association that can promote professional development and leadership in the field. The Ethiopian Library Association (ELA) was first established as a library club in 1961. It was then registered and achieved its official status in 1969. ELA was unable to play its role because of bad image of the profession, migration of professionals to the West, and dissatisfied professionals. Presently, ELA does not exist as a professional organization; however, there is a movement toward reestablishing the association.^[22] Just a year ago a new library, archives and

information systems association was formed which was sponsored by the British Council and is called Ethiopian Library, Information Science and Archives Professional Association.

THE NATIONAL ARCHIVES

The National Archives of Ethiopia was established in 1979 as a main division of the NALE. The main objectives of this section were to gather and store documents of historical importance. In 1999, by virtue of proclamation 179/1999, the National Archives was clearly separated from the National Library in spite of the fact that it is housed in the same building with the National Library and still shares the same Board of Directors. The new responsibilities it has assumed are wider in scope. Some of its responsibilities are cataloging all the newly gathered materials: collecting chronicles, letters, historical documents and photographs, articles and research papers, correspondence, publications, maps, and materials concerning law and the judiciary; preserving priceless archival materials exposed to dangers (such as publications at an organization that is defunct or closed); and preventing any archival materials from being taken out of the country.

Currently, the National Archives houses 3218 folders of archives, 537 Plans and Maps, 665 bound audit and financial matters archives, and 2487 photographs. In addition, under special custody, it has 422 files and 38 bound archives. When considering the sources of these archival materials, the first collection came from the Ministry of the Grand Palace, Palace of the Crown Prince, and others. The collection of the National Archive includes letters by Ethiopian Kings, such as Emperor Thewodros' letter (1855–1868) to Queen Victoria explaining misunderstandings between the two; Emperor Yohannes IV's letter (1872–1889) to Queen Victoria explaining the threat his country faced with Muslims; and Emperor Menelik II's (1889–1893) letter to Nicolas II of Russia about his victory against the invading Italians and his interest in fostering the relationship between their countries. Most of the archival items collected are in Amharic, Geez, French, Italian, English, and Arabic.

As mentioned earlier, the origins for the collection of the National Archives are a wide range of organizations and private collections housed in individual residences. The Archive Repository and Research section was required to sort out and move all the items that were stored in the Prime Minister's office. These documents cover the administrations of Emperor Menelik (1889–1913), Lij Iyassu (1913–1916), Empress Zewditu (1916–1930), Haile Selassie I (1930–1974), Mengistu Hailemariam (1974–1991), and the current Prime Minister, Melesse Zenawi.

In addition, in the 1980s and 1990s, the National Archives collected materials from private sources. For

instance, in 1981 the National Archives acquired the personal archives of Dejazmach Zewde Gabre Sellassie, who served as departmental attaché in the Ministry of Foreign Affairs, mayor of Addis Ababa and who also held other positions in other ministries. Some of the valuable items that were transferred are maps and archives in Amharic, English, Italian, French, Geez, and Tigrigna. The collection consists of handwritten, typed, and published materials.^[21]

The second individual collection that was transferred to the National Archives was that of Aleka Taye Gabre Mariyam. The National Archives acquired it in 1993. The significance of the transfer of this collection is that Aleka Taye was a famous intellectual who served as instructor of Amharic and Geez languages, visited many countries, and befriended royalties. Most of the materials in his collections were handwritten, including the Book of Philosophers, the History of the Wanderer, the History of the Royalties in Geez, and the Book of Religion.^[23]

The third valuable archival material that was transferred was the collection of Dejazmach Kebede Tessema who served as a palace attendant, the first mayor of Addis Ababa, vice-member of the legislative body, and vice-president of the same legislative body. His collection includes research conducted to alleviate prostitution, and letters he exchanged with various patriots since 1940.^[23]

Finally, the fourth significant collection that was transferred to the National Archives was the collection of Bilata Mersie Hazen Wolde Kirkos, who served as a teacher, school director, Secretary of the Commission formed to resolve the British–French border dispute in French-Somaliland, and High Court judge. His collection comprises a historical account of ministerial appointments in Ethiopia and a list of ministers appointed, an account of confrontation between Egypt and Ethiopia, and the history of the national flag.^[23]

The National Archives issues guidebooks and calendars for its users. Guidebooks are items that provide information on the available archival materials that are owned by the National Archives whereas calendars list the archival materials compiled on the basis of the guidebooks.^[23]

MUSEUMS AND GALLERIES

Museums and galleries are the two types of institutions that collect and preserve cultural objects of a society. In most cases, museums are cultural centers where public properties are housed whereas galleries are privately owned for the purpose of collecting and exhibiting art objects. In addition, the main purpose of galleries seems to be promoting emerging artists and selling their works to art collectors and museums (in its current use of the term in Ethiopia).

The emergence of museums and galleries in Ethiopia goes back to the introduction of Christianity to the country in fourth century A.D. Since that time, religious centers,

such as churches and monasteries, became custodians and preservers of ethnographic and religious objects. The emergence and growth of museums in Ethiopia can be divided into three periods: 1) from the formative period until the occupation of the country by Italians (1936–1941); 2) from the liberation to 1974 when the revolution started; and 3) the expansion of museums since 1974.

Museums

The shaping of museums before the Italian occupation

As mentioned earlier, the collection and preservation of cultural items in Ethiopia seems to begin after Christianity was introduced in the fourth century A.D. Some of the items that were gathered by the religious institutions include clothes, books, parchments, paintings, and crosses (either religious or secular in type). Kings and members of the ruling class also kept items of historical importance in their own private collections. The major problem with church or private collections was access to them by the general public. However, the endeavor to systematically collect objects of historical importance started during the reign of Menelik II immediately after the Battle of Adwa (1896). One of the reasons for the development of museums and galleries was the interest exhibited by foreigners, who came especially to Addis Ababa, for art works. According to Professor Richard Pankhurst,^[4] the only person who opened a gallery and sold art objects was a certain Greek named Giyorgis, who fought against Italians alongside with Menelik II in the Battle of Adwa. In addition, this demand by travelers for art objects created cultural awareness among the local people at the same time.

The emergence of museums in Ethiopia was further advanced by the archaeological discoveries carried out by Europeans. The first one was a German Expedition that came to the north city of Aksum in 1906. Moreover, in the 1920s and 1930s, a group of artists who were educated in painting in France returned to the country. This created a demand for their products. The efforts of systematically collecting and preserving cultural and historical objects continued to grow under Haile Selassie I, who signed a cultural and scientific agreement with the French government. More importantly, the temporary occupation of Ethiopia during World War II had fundamentally changed the demand for and supply of touristic objects and this development was also seen as a new dimension of economic benefits among artists.

Development of museums from 1941 to 1971

The second major stage in the growth of museums and galleries was the time period between 1941 and 1974. The first significant step that was taken by Haile

Selassie I was the organizing of a museum-like section that was attached to the National Library in 1944. In this section, precious objects of high value representing the ruling class members were stored, including cloaks, ceremonial clothes, and household objects. This led to the establishment of what is now called the National Museum of Ethiopia (Fig. 2; it seems nobody knows when this name was actually given to the museum-like building).

The second significant stage in the development of museums and galleries in Ethiopia during this period arose when the University College of Addis Ababa (UACC) was opened in 1950. Soon after its opening, the UACC began to sign cultural agreements with foreign governments. For instance, in 1952, UACC signed a cultural agreement with the French government that allowed the French archaeological mission into the country in 1954. The mission performed its archaeological excavations in the northern part of the country (Tigray and Eritrea).

The 1906 German and 1950s French archaeological missions were rewarded with rich archaeological findings that included potteries, stone tools, and inscriptions.^[4] Quite a number of their findings are now exhibited and preserved in the National Museum and Aksum Archaeological Museum, whereas some are stored in a facility near the Archaeological Museum in the city of Aksum.

Another important event in the development of museums and galleries in the 1950s was the celebration of the Silver Jubilee of the imperial period of Emperor Haile Selassie I. He invited foreign heads of states and other dignitaries to witness this celebration. For this event, he wanted an exhibition on the rich heritage of Ethiopia. UACC was given the responsibility to organize such an exhibition.^[24] The Chief Librarian at UACC at that time, Professor Chojnacki, commenced to direct the collection of cultural objects from the different ethnic groups of the country through students (the students did some of the collecting). The efforts of gathering cultural objects from the various ethnic groups were also aided by the Ethnological Society (a professional association of scholars) that was established in 1951.^[25] This in turn led to the creation of the Institute of Ethiopian Studies Museum in 1963 in Addis Ababa (Fig. 3).

Finally, there were two other national and international events that played important roles in the development of museums in Ethiopia. The national event was the small exhibition of 1958 that displayed the cultural items that were discovered by the German and French archaeological excavations conducted in the northern part of the country. The emperor himself visited the exhibition. This particular event at the same time increased the awareness of the public and led to having a permanent exhibition open to the general public. The international event that indirectly had an important role in the development of museums was that Ethiopia increasingly became a center for African and

Fig. 2 National museum of Ethiopia.

international affairs. The Organization of African Unity (OAU) was established on May 25, 1963. The Emperor wanted an exhibition to be organized at the university for this historic moment, and the responsibility was assigned

to the then University Librarian Professor Chojancki. This resulted in the founding of the Institute of Ethiopian Studies and its museum as well. The items displayed in this museum include

Fig. 3 The institute of Ethiopian studies.

icons, triptychs, diptyches, religious and folk paintings, processional crosses, hand crosses, neck crosses, miscellaneous church objects as far as religion and art were concerned while its objects of material culture include agricultural implements, basketry, gourds, horn and ivory ware, leather objects, jewelry, metal objects, musical instruments, national costumes, outdoor life objects, pottery, weapons, other objects not classified.^[25,26]

An important fact to mention is that the archaeological artifacts collected by the expeditions accumulated over time. Thus, citizens of Ethiopia wanted to know the past and there was a need to open a museum where the items could be displayed for the general public to view. This is the third stage in the development of museums in Ethiopia in the mid-1960s when the Ministry of Finance transferred the former office of the Ministry of Foreign Affairs to the National Museum on a temporary basis. Even at this time, there still is no law that formally establishes a national museum in the country. In 1966, the imperial government passed a proclamation that established the Office of Archaeology and Antiquities Administration as a result of the increasing archaeological findings that require proper preservation and handling for future researchers.

Finally, in 1968, there was a new milestone in the development of museums in the country. The Society of Friends of the Institute of Ethiopian Studies Museum (SOFIES) was founded as an organization that assumed the responsibility for collecting Ethiopian cultural objects within or outside the country, by organizing fund-raising activities in order to buy them back.

In summary, the development of museums in Ethiopia during the imperial time was modest. There were no plans or visions how to establish and run them. We can say they are mainly the products of the tremendous amount of artifacts uncovered by the archaeological missions conducted by foreigners and the interest showed by SOFIES.

Development of museums since 1974

In 1974, the military junta known as the Dergue overthrew the regime of Emperor Haile Sellassie I and assumed power until 1991. It was during this period that many ethnographic museums began to emerge in the different parts of the country. However, the development and the growth of the galleries took a different path as they were privately owned.

Some of the ethnographic museums that were established during this period include the Wollega Museum, the Harar Museum, the Dessie Museum, the Mekele Museum, and the Jimma Museum even though it was created earlier in 1973. The majority of these museums were founded with cultural objects collected by the different communities in their respective regions. In addition, in the capital city, Addis Ababa, another historical and ethnographic museum was founded in 1984.

We attempt to provide a brief description of these ethnographic museums here below.

The Addis Ababa Museum was first established in 1984 in dedication to the Founding Congress of the Workers Party of Ethiopia (WPE) on the tenth anniversary of the Ethiopian Revolution. Then, it became the city museum in 1986 during the centenary anniversary of its founding. The museum's exhibition consists of items that reflect the culture, social affairs, health, education, and housing and urban development of the city. In addition, the armed forces exhibition displays the Ethiopian national struggle against foreign invaders and aggressors and the growth of Ethiopia's modern armed forces.

The Jimma Museum is located about 340 km southwest of the capital city. It was in 1973 when the then Emperor Haile Sellassie I visited the city of Jimma that the collection of the cultural objects began. In 1989/90, the local office of the Ministry of Culture acquired these collections and started to run it as a museum. The museum currently displays royal objects from the local king Jimma Aba Jifar (1878–1932), cultural objects from the various areas in the region, Koran Holy Books on parchment, Christian Holy Books also on parchment, and paintings.^[4]

The Wollega Museum was created in 1987 and is located 334 km west of Addis Ababa. The items collected for this museum predominantly represent the Oromo culture and the early rulers of the kingdom. The museum building is one of the two buildings in the country that show the architectural design of a museum. The objects in this museum include royal objects of the rulers of the kingdom, traditionally curved wooden chairs, photographs, and paleoanthropological and geological items.^[27]

The Dessie Museum is located in the city of Dessie which is 400 km from the capital city. It was established in 1981. This museum displays fossils, bones, ancient manuscripts, weapons captured from the Italians during the battle of Adwa, pottery, handicrafts, ethnic costumes from the area around, a book written in Arabic about the introduction of Christianity, wooden products, musical instruments, leg bracelets, necklaces and neck crosses, baskets, and artifacts from King Mikael, Menelik II, and Haile Sellassie I.^[27]

The Mekelle Museum (Yohannes VI) is another ethnographic museum located north of the capital. It was established in the compound of the palace of Emperor Yohannes IV (1872–1889). The items on display include clothing of dignitaries, family pictures of the Emperor, his bed, a jar, containers made of goat skin, ceramics, books, neck crosses, bracelets, a gold-plated knife, and a statue of Mussolini in front of the museum.

Finally, the Harar National Museum and Community Museum, created in 1981, are located in the eastern old city of Harar. The Harari (an Ethio-Semitic ethnic group) Community Museum houses cultural objects that completely represent its own ethnic group whereas the items displayed in the Harar National Museum come from

the various ethnic groups that are found in the region. The items exhibited in the two museums include pottery, gourd, and wood-cut products.^[27]

In summary, during the time of the Dergue and thereafter, museums saw a modest growth in the country. However, this growth cannot be enough when considering the many ethnic groups that exist in the country.

An Overview of the Development of Galleries

The beginning of galleries in Ethiopia is associated with the two brothers Assefa and Serek Yimaneberhan. They were graduates of the Menelik II Secondary School which had a painting and art training section. They had informal training by their father who was a traditional painter. After they had completed their school, the two brothers opened an art gallery, or some prefer to call it an art studio at Arat Kilo (just on the opposite side of their school) in the 1950s. Their works were not sold to the general public but they were commissioned to paint by the various offices of the military and prominent individuals. This gallery closed because of financial difficulties the two brothers faced in the 1950s.^[27]

In another development, foreigners who resided in the country had keen interest in art works in the country. Some of them had the opportunity to open their own art galleries. One such gallery (souvenir shop) worthy of mentioning was the one opened by Madam Riva of Italian origin in 1957/1958 in Addis Ababa (Piazza area). Her shop sold paintings and antiquities of Italian, Greek, Ethiopian, and other origins.^[27]

The second foreigner to open another gallery in the country was an Armenian. It was opened in the early 1960s. It was called Belvedere Gallery and was organized in a better way than the earlier one. It is in this gallery that Ethiopian artists began to display their works to the general public for the first time. The gallery continued to play that role until the 1974.

The development of galleries in the early 1970s started to decline. This decline could be attributed to the political situation that prevailed in the country at that time. In 1974, the Emperor was overthrown by the military and soon after a Marxist style of government that discouraged private ownership of property was formed. Thus, the role of the galleries was taken over by big hotels and foreign cultural centers, such as the Alliance Française, the German Cultural Center, and others. Artists commenced to use these new venues to exhibit their works.

Currently, there seems to be a significant increase in the growth and development of galleries in the country. The regime that is in power has created a suitable atmosphere for private investment and ownership of private property. As a result of this, galleries have started to reemerge in the country. One of the galleries that operates at this time is St. George Interior Decoration and Art Gallery that was

founded in 1991. The gallery displays traditional tables, chairs, headrests of kings, decorated cotton clothes, jewelries, and modern and traditional paintings. The gallery acquires its cultural objects from different parts of the country.^[28]

In 1996, another gallery named Goshu Art Gallery was established in Addis Ababa. The owners of the gallery, who are artists themselves, opened it in order to promote artists and art in the country. The items exhibited in the gallery include traditional and modern paintings, sculptures from West Africa, masks and decorated vases from Yemen, and household items with Ethiopian touches. In addition, the owners use this gallery to exhibit their own art works.^[27,29]

Another art gallery that was also created in 1996 was Asni Gallery. It is housed in a traditional villa in Addis Ababa whose architecture is very interesting by itself. This art gallery features modern art. The last gallery is the Universal Arts and Crafts that was opened in 2000 in Addis Ababa too.^[27] The gallery displays household ornaments, African art, Imperial Furniture, oriental art, lampshades, and paintings.^[27] These are some of the significant galleries that are found mainly in the capital city Addis Ababa.

The development of museums and galleries in Ethiopia shows the same kind of problems shared by the National Library and Archives. The first and the most important problem is a lack of financial support coupled with a shortage of professionally trained manpower. In addition, the museums lack space for the objects to be properly displayed to the people who come to visit them.

In conclusion, the development of the National Library, National Archives, and museums and galleries requires proper planning, financing, trained-manpower, and legislation in order for the country to successfully utilize its rich cultural heritage. There are some indications pointing to this direction, but it needs a real commitment from the government, the people, and other organizations that have a stake in it.

Everyday Life Information Seeking

Reijo Savolainen

School of Information Sciences, University of Tampere, Tampere, Finland

Abstract

Information seeking may be analyzed in two major contexts: job-related and nonwork. The present entry concentrates on nonwork information seeking, more properly called everyday life information seeking (ELIS). Typically, ELIS studies discuss the ways in which people access and use various information sources to meet information needs in areas such as health, consumption, and leisure. The entry specifies the concept of ELIS and characterizes the major ELIS models. They include the Sense-Making approach (Dervin), the small world theory (Chatman), the ecological model of ELIS (Williamson), ELIS in the context of way of life (Savolainen), the model of information practices (McKenzie), and the concept of information grounds (Fisher). ELIS practices tend to draw on the habitual use of a limited number of sources, which have been found useful in previous use contexts. Since the late 1990s, the Internet has increasingly affected the ELIS practices by providing easily accessible sources. Even though the popularity of the networked sources has grown rapidly, they will complement, rather than replace, more traditional sources and channels.

INTRODUCTION

Information seeking is a major constituent of information behavior or information practices, that is, the entirety of ways in which people seek, use, and share information in different contexts.^[1–3] Information seeking may be analyzed in two major contexts: job-related and nonwork. The present entry concentrates on nonwork information seeking, more properly called everyday life information seeking (ELIS). Typically, ELIS studies discuss the ways in which people use various information sources to meet information needs in areas such as health, consumption, and leisure.

Due to space restrictions, the present entry focuses on ELIS research conducted in the field of information studies or library and information science since the 1990s. First, for this reason, certain types of studies relevant to ELIS will not be discussed. These studies include marketing and consumer research, communication studies (e.g., audience research), and public library use studies. Second, specific questions of ELIS such as search strategies during interactions with Internet search engines will not be considered in the present entry. The entry is structured as follows. In the next section, the concept of ELIS will be clarified. Then, the ways in which various sources and channels are used in ELIS will be discussed, and the major conceptual models of ELIS will be characterized. The last section concludes the entry.

THE CONCEPT OF ELIS

Thus far, a rich variety of themes has been explored in ELIS studies. They have focused on people belonging to diverse groups such as the following:

- Young adults^[4–6]
- Adolescents making career decisions^[7]
- Elderly people^[8,9]
- Abused or battered women^[10,11]
- Women struggling with overweight^[12]
- People diagnosed with cancer^[13,14]
- Homeless parents^[15]
- Unemployed people^[16]
- Immigrants^[17–19]
- Hobbyists of various kinds, for example, amateur genealogists, coin collectors, and cooks^[20–23]
- Environmental activists^[24,25]

As these examples suggest, the phenomena of ELIS can be approached from a number of viewpoints, for example, by concentrating on the demographic features of information seekers, or investigating information needs and seeking of young people. The issues of ELIS can also be explored by focusing on the problems faced by people, for example, losing one's job, or having a chronic disease such as diabetes. Finally, ELIS can be investigated in the context of leisure activities such as hobbies.

Particularly in the early years of ELIS research, concepts such as citizen information needs and seeking were utilized to denote information seeking taking place outside work tasks.^[26] Even though the concept of citizen information needs and seeking is illuminating in itself, it is rather narrow because it primarily refers to people's rights and obligations toward social institutions as voters or participants in activities of civil society. Alternative concepts such as nonwork information seeking are problematic due to its residual nature and negative connotations: nonwork information seeking is implied to be less significant because it deals with

something that is not associated with daily work.^[27] The definition problem is further aggravated by the fact that issues of job-related and nonwork information seeking tend to overlap and they may be interwoven in everyday settings.^[28] For example, seeking information about computer courses may serve both professional ends and hobbies.

Terminological problems originating from the false dichotomy of work-related and “nonwork” information seeking may be avoided by taking the concept of ELIS as starting point.^[27] The key word is everyday life, which refers to a set of attributes characterizing relatively stable and recurrent qualities of both work and free time activities. The most central attributes of everyday life are familiar, ordinary, and routine, and they qualify the structural conditions of action (e.g., the recurrent “rhythms” of work and leisure hours). These characteristics of familiar, ordinary, and routine become real only in the process in which they are reproduced, day after day.

From this perspective, information seeking may occur in both work-related and leisure-related contexts of everyday life. Because the field of work-related information seeking is relatively well defined and the term work-related information seeking is self-explanatory, usually there is no need to use the more specific expression of “work-related information seeking in the context of everyday life.” Thus, the concept of ELIS may be reserved to denote information acquisition taking place in less clearly specified contexts and activities such as hobbies and household care. These activities and contexts are seen as important in their own right; they are not only residuals of work-related phenomena. Hence, the positive term ELIS indicates that ELIS is not inferior to work-related information seeking.

Generally defined, the concept of ELIS refers to the acquisition of various informational (both cognitive and expressive) elements, which people employ to orient themselves in daily life or to solve problems not directly connected with the performance of professional tasks or full-time study.^[27] Similar to work-related information seeking, ELIS may have two modes. On the one hand, ELIS may refer to seeking of problem-specific information (e.g., finding a fact). On the other hand, ELIS may manifest itself in the seeking of orienting information (i.e., monitoring of everyday events by using various sources and channels).

EVERYDAY INFORMATION NEEDS

A considerable number of ELIS studies focus on the ways in which information sources are used to meet various information needs. The specificity of research settings varies from general-level surveys of source usage to studies on ELIS focusing, for example, on health issues.^[29–31] However, due to space restrictions, the present entry concentrates on general-level studies.

Strictly defined, the tradition of ELIS research dates back to the early 1970s, when extensive surveys were launched in

the United States to investigate ordinary people’s information needs and seeking. At that time, the first attempts were made to elaborate conceptual and methodological tools for ELIS studies. Marcia Bates^[32] pioneered by introducing the concept of life information in 1974: By “life information” is meant information needed for successful living. The area of need ranges all the way from sheer survival (stay away from dogs that walk funny and foam at the mouth) to the most advanced forms of self-realization (where can I study ceramics or transcendental meditation?). Thus defined, the aforementioned concept includes “vast amounts of information about how to do many different things in one’s culture that will be acceptable and lead to one’s survival and emotional satisfaction.”^[32]

Somewhat later, Brenda Dervin, a communication scholar, created innovative approaches to enrich traditional ELIS survey research settings. Douglas Zweizig also contributed significantly to methodological issues, primarily in the field of public library use studies.^[33,34] One of the pioneering surveys of ELIS was based on interviews with about 1000 people in Baltimore in 1972. The informants represented various demographic groups. This massive study revealed almost 9000 everyday life questions or problems reported by the interviewees. These problems were categorized into problem areas indicating daily information needs as follows:^[35]

- Neighborhood
- Consumer habits
- Housing and household maintenance
- Crime and safety
- Education
- Employment
- Transportation
- Health
- Recreation
- Discrimination
- Financial matters
- Legal problems
- Public assistance

Later surveys have demonstrated that these need areas are largely also valid today. For example, a nationwide project on citizenship information conducted in Great Britain in 1997 revealed similar areas of everyday information needs.^[36] Apparently, the major information need areas are relatively stable, and the variation between (Western) countries is rather insignificant.

THE USE OF INFORMATION SOURCES

ELIS studies have also identified the most popular information sources and channels used to meet people’s information needs. Traditionally, human sources are preferred in ELIS. An extensive telephone survey conducted in

New England, the United States, in 1979 showed that three out of four respondents had drawn on their own experience in problem solving; in addition, friends, neighbors, and relatives appeared to be popular sources.^[37] Later studies have demonstrated that people tend to favor familiar sources such as newspapers, television news, and health professionals because they have functioned well in earlier use contexts.^[38] Overall, ELIS seems to be characterized by a conservative attitude: people tend to draw on familiar information sources that are often used almost routinely.^[38]

Since the late 1990s, particularly e-mail and World Wide Web (WWW) have been widely accepted as new tools for communication and information seeking. The surveys indicate that people use the networked services for various purposes (e.g., keeping in contact with others by e-mail, seeking health information from web pages, buying products and services, and participating in online discussions).^[38–40] For example, a study conducted in Sweden demonstrated that in the early 2000s, the Internet had already gained a fairly significant place in the informants' communication and information-seeking practices, providing a wide variety of sources for different purposes of use.^[41] The Internet was also found to be useful as a source of market information (e.g., flight schedules, car rentals, objects for sale, and job opportunities). The preference for the networked sources was also strengthened by the availability of search engines such as Google.

Along with the development of Web 2.0 technologies, the forums of social media have become increasingly popular in ELIS. These forums provide user-generated content (UGC) such as blog postings, answers available on social reference sites, and Wikipedia entries that can be used to support everyday problem solving and decision making. Empirical studies have demonstrated that blogs and online discussion forums can provide useful sources of information for people struggling with health problems, for example.^[42,43] In addition, social media forums such as Question & Answering (QA) services, for example, Yahoo! Answers, and virtual communities such as *Tripadvisor* have gained popularity as sources of ELIS.^[44,45] Even though UGC can provide rich sources of information since UGC originates from "real experiences by real people,"^[46] the credibility of UGC may be an issue because it is often a mixture of fact and opinion, impression and sentiment, founded and unfounded tidbits, and experience.^[46] Although the networked sources have gained popularity, the Internet has not been able to replace other media such as the telephone, television, radio, and newspaper with ELIS. On the contrary, the network sources and services complement them both in job-related and nonwork contexts.^[47,48]

THEORIES AND MODELS OF ELIS

Compared to job-related information seeking, the number of theoretical frameworks and models of ELIS is still quite

low. This is partly due to the relatively short tradition of this subfield and the smaller number of researchers who are active in ELIS issues.

The Sense-Making Methodology (Dervin)

Brenda Dervin can be counted among the most influential researchers of ELIS since the early 1970s. Her early studies focused on the communication practices of urban poor people.^[49] In the early 1970s, Dervin began to develop the sense-making approach as a methodology focusing on human communication and the design of communication-based systems and activities. Since then, the theoretical and methodological bases of the sense-making approach, currently referred to as sense-making methodology (SMM),^[50] have been transformed and refined. The SMM has been applied in numerous contexts to explore information needs and seeking of specific groups of people.^[50–52] Dervin employs the metaphors of situation, gaps, and uses to depict information seeking and use them as a sense-making process. Metaphorically, the situation stands for the time–space context, where the individual becomes aware of the insufficiency of one's earlier definition of a situation. Gaps refer to questions or information needs elicited in situations of this kind. Uses stand for the ways in which information being sought or received from various sources helps to bridge the gap and to create a new sense. Examples of uses include getting ideas and understanding, being able to plan ahead, deciding what to do, and getting out of a bad situation.^[51] More generally, information seeking and use may be approached by drawing on the metaphor of gap-bridging. However, this metaphor does not suggest a substantive conception of information seeking and use. The metaphor gives methodological and heuristic guidance to posit contextual questions as to how people interpret information in order to make sense of it. These questions focus on the ways in which cognitive, affective, and other elements useful for sense-making process are constructed and shaped in order to bridge the gap.^[50–55]

Although the SMM draws heavily on metaphorical formulations, it has gained empirical support. It strengthens the hypothesis that information seeking is a constructive process based on the utilization of categories of situation, gaps, and uses. For example, a study focused on blood donors who were asked to describe the process of donating: What happened first in the donating situation? What are the questions they themselves posed? How did they hope the answers to their questions would help them?^[56] Other sense-making studies have focused, for example, on the information needs and seeking of cancer patients.^[57] The SMM has inspired, for example, Julien's investigation focusing on barriers to adolescents' information seeking for career decision making;^[7] and the study of Pettigrew et al.^[58] reviewing the ways in which people use public library-community network systems.

In sum, the SMM has contributed significantly to the conceptual and methodological development of ELIS research. By emphasizing the role of individuals trying to bridge gaps in everyday situations and the nature of information as a situation-bound human construct, sense making has advocated the user-based approach, as opposed to the traditional information system-centered viewpoint. Thus, Dervin has not only introduced a new viewpoint to ELIS studies but has also more broadly contributed to the theoretical and methodological breakthrough of the user-centered approach to information-seeking studies.^[59]

ELIS in the Context of Small World (Chatman)

Elfreda Chatman is one of the most distinguished researchers in the field of ELIS studies. In the 1980s and 1990s, she conducted a highly original ethnographic research project focusing on information-seeking behavior of people living in the margins of society. The project was characterized by an attempt to develop a genuine social scientific theory, which describes ELIS in the context of “small world.” This concept refers to social environments where individuals live and work, bound together by shared interests and expectations, and often economic status and geographic proximity as well.^[60] In small-scale communities of these kinds, activities are routine and fairly predictable. Everyday information seeking and sharing are oriented by generally recognized norms and role expectations based on beliefs shared by members of the community.

Chatman explored ways in which poor people seek, use, and communicate information within the context of their everyday settings. In a study characterizing the information world of low-skilled workers, Chatman^[61] examined the information needs and seeking behavior of female janitors at a university. It appeared that they had a narrow, concrete, and local view of the world restricted to the most familiar social milieu. Thus, information originating outside of this “small world” was not of great interest to them. The repertoire of information sources appeared to be narrow. Much daily information came from television. To some extent, information was also sought in newspapers. Most informants felt that personal experience was the most reliable source of information. They favored “first-level information” received through personal experiences or hearsay from someone who is accepted as having knowledge of the matters to be discussed. In contrast, the value of “second-level” information received from outsiders was suspected and often ignored because this type of information is not compatible with the common sense reality of the small world.

The specific features, characteristic of information seeking in the small world, were also studied among elderly women residing in a retirement complex.^[62] Ethnographic analysis was conducted to ascertain their information and recreational needs and to explore the most

popular information sources. The informants appeared to be active users of mass media. In contrast to the janitor study, the informants of this study favored quality TV programs, and they read books and magazines quite frequently but were not active users of public library.

Based on the aforementioned studies, Chatman^[63] concluded that everyday information seeking of small world people is affected by four major factors forming the basis of the theory of information poverty: risk taking, secrecy, deception, and situational relevance. For example, the women of the retirement community avoided risk taking by not telling anyone about declining health concerns, thus giving up to seeking information or gaining emotional support.^[63] The notion of secrecy is closely related to risk taking in that the elderly women concealed physical and mental ailments. Third, deception represents a deliberative attempt to act out a false social reality.^[63] In this way, one engages in activities in which personal reality is consciously and forcefully distorted, and the individual tries to appear better than one really is. Finally, situational relevance is instrumental in explaining information poverty. Potentially useful information will be not used because people living in a small world do not see a generalized value of sources provided by outsiders intended to respond to their situation. The source is ignored because it is not legitimized by “contextual others.”^[63]

To specify the ideas of small world, Chatman^[64] developed “a theory in the round,” based on the ethnographic study of female prisoners. The concept of “life in the round” refers to a dynamic world based largely on approximation; in this world, things are understood implicitly.^[64,65] When people live in the round, imprecision is largely accepted and inexactitude is tolerated. In this context, “members move in and out of the round depending on their need for more systematic, precise, and defined information.”^[66] Understanding life in the round results when information is clear enough to give sensible meaning to things. The most important consequence of this construct for the practice of ELIS is that life in the round adversely affects information seeking in day-to-day situations; people will not search for information if there is no need to do so. Small world inhabitants ignore information if they perceive that their world is working without it (i.e., they have enough certainty, comfort, and situational predictability so that the need to seek information is negated).^[66] Individuals will cross information boundaries only if 1) information is perceived as critical, 2) there is a collective expectation that the information is relevant, and 3) a perception exists that the life lived in the round is no longer functioning.^[64]

Chatman^[67] summarized the theoretical developments in a theory of “normative behavior.” The theory may be seen as an elaboration and extension of the theory of life in the round. In brief, the normative theory of behavior suggests that ELIS is affected by the worldview and norms characteristic of specific communities. In addition, ELIS is

affected by the ways in which actors are classified into insiders or outsiders. Ultimately, norms and roles determine what kind of information sources will be preferred, accepted, and used.

Chatman's research project on the information-seeking practices of marginalized people inspired other projects (e.g., the study of Hersberger^[15] focusing on the ways in which homeless parents living in family shelters seek for everyday information). The research line opened by Chatman is promising both theoretically and methodologically. Importantly, Chatman's research project exemplifies the genuine need to utilize the repertoire of social scientific theories and ethnographic approaches to enhance our understanding of information seeking as an integral part of everyday action in social contexts.

The Ecological Model of ELIS (Williamson)

By drawing on the findings of an empirical study in which some 200 older adults were interviewed in Australia in 1992–1994, Kirsty Williamson^[8,68] developed an ecological model of information seeking and use. It can be called ecological because it sets information seeking and use in the context of social and cultural factors, which may have an influence on the ways of selecting and using information sources and channels. The model suggests that, although people purposefully seek information in response to perceived needs, they also monitor their world and receive information incidentally. The ways in which they monitor the everyday world is mediated by social-cultural backgrounds and values, physical environments, and personal characteristics (e.g., their states of health), as well as their socioeconomic situations and lifestyles.

The model suggests that in purposeful and incidental information seeking, information sources of various types are given differing importance. The intimate personal networks (family and friends) are closest to the user and are probably also perceived by the user as most easily accessible. The other source types are located farther in the "ecology of sources" [i.e., wider personal networks (clubs, churches, and voluntary organizations) and the mass media (newspapers, television, radio, and magazines)]. Institutional sources such as professionals, government departments, and other organizations are perceived to be even more remote in this sense. The ecological model has been applied in empirical studies focusing on ELIS of diverse groups such as blind and visually impaired people.^[69] The strength of the ecological model is that it allows information seekers to be conceptualized as both individuals and members of social groups. The model also takes into attention the influence of particular physical and social environments. The individual is seen as a creative and thinking entity, but within contexts that involve various kinds of biological and social constraints.

ELIS in the Context of Way of Life (Savolainen)

"Way of life" is a social scientific concept that provides a broad context to investigate individual and social factors affecting ELIS. Reijo Savolainen^[27] defined the concept of way of life as "order of things," which is based on the choices that individuals make. "Things" stand for various activities taking place in the daily life world, including not only jobs but also necessary reproductive tasks such as household care and voluntary activities (hobbies); "order" refers to preferences given to these activities. Because, in most cases, the order of things is a relatively well-established constellation of work and nonwork activities taking place in a day or a week, this constellation is easily taken to be the most natural or normal way of organizing one's everyday life. Correspondingly, people have a "cognitive order" indicating their perceptions of how things are when they are "normal." Through their choices, individuals have practically engaged in a certain order of things, and it is in their own interest to adhere to that order as long as they find it meaningful. Thus at least implicitly, most people seek for an internal coherence in everyday matters because it gives them better chances to plan their choices and act meaningfully.

The most central issues of way of life manifest themselves in the structure of the time budget, described as a relation between working and leisure time, models of consumption of goods and services, and nature of hobbies.^[27] The structure of the time budget reveals the proportions of time spent on work, necessary activities outside work such as household care, and, finally, the time devoted to recreational activities such as hobbies. By analyzing the models of consumption, one may draw a picture that indicates the share of money spent on the acquisition of various goods or services (e.g., books). The analysis of hobbies sheds light on the substance of way of life because the nature of hobbies informs us of the things that people find most pleasant. The analysis also reveals the role of informational interests (for instance, newspaper reading) in leisure time.

Because the meaningful order of things may not reproduce itself automatically, individuals are required to take active care of it. This caring activity can be defined as mastery of life, implying the importance of the coherence of the everyday life projects at large. The nature of these projects may vary. As aptly specified by Hektor,^[41] some life projects may be generic in that they are common to most people (e.g., household care). Other projects are specific because they originate from an individual's life situation (e.g., child rearing or one's specific interests, i.e., hobbies).

Mastery of life serving one's life projects may be either passive or active. It is passive when people are satisfied with seeing that everything is going on as expected, at least on the whole.^[27] Active mastery of life is associated with pragmatic problem solving in cases where the order

of things has been shaken or threatened. Mastery of life is a general preparedness to approach everyday problems in certain ways in accordance with one's values. Information seeking is an integral component of mastery of life, which aims at the elimination of continual dissonance between perceptions of "how things are at this moment" and "how they should be." If there is no dissonance, mastery of life goes on quite routinely and the information seeking attached to it can be characterized as a rather passive monitoring of everyday life events. In other cases, mastery of life may grow into active problem solving aimed at restoring the disturbed order, usually requiring active seeking of practically effective information.

Savolainen^[27] utilized the aforementioned model in an empirical study conducted in Finland. The study focused on two groups: teachers and industrial workers. The empirical study strengthened the assumption that way of life directs information seeking in a significant way. Teachers were more eager to seek factual information from various media, and they took a more critical stand toward the supply of light entertainment from radio, television, newspapers, and magazines. The interviews revealed that personal interest and current life situation also affect media use. There appeared to be teachers not particularly interested in the culture or politics sections of newspapers; similarly, some workers preferred documentaries and other serious programs and took a critical view of entertainment.

Later on, Savolainen^[38] elaborated the aforementioned framework into the model of everyday information practices. This model differentiates three modes of everyday information practices: information seeking, information use, and information sharing. The model makes use of the ideas of social phenomenology^[70] by approaching information seeking, use, and sharing in the context of life world in which everyday projects of diverse kinds are embedded. For example, looking for a new job and concern for the environment exemplify such projects. Everyday information practices may serve as tools to achieve the goals of these projects. Furthermore, the model suggests that the concept of information source horizon is central for the constitution of everyday information practices since this horizon indicates the ways in which people prefer information sources and thus navigate the information world. The ideas of the model were used in an empirical study examining information practices among environmental activists and unemployed people.^[38]

Information Practices (McKenzie)

One of the newest models of ELIS is proposed by Pamela McKenzie.^[71] The model was developed in the context of health information seeking by pregnant women. McKenzie specifies a two-dimensional model of context-bound information practices. The model describes four modes: active seeking, active scanning, nondirected monitoring, and

obtaining information by proxy. When seeking information, the modes may appear in varying order, depending on the information need at hand and the situational factors. The modes can take place in two phases: first, at times of connecting information sources; and, second, interacting with them. Thus, the second phase implies the use of the information source to which one has been connected. The indications of use are, for example, reading a text or actively asking specifying questions when consulting a doctor.

By drawing on the aforementioned model, the process of health information seeking may be described as follows.^[71] Active seeking can be defined as the most directed mode of information practice. Consulting a previously identified source (e.g., a family physician), re-reading an entry in an encyclopedia, or conducting a systematic known-item search in a medical database exemplifies active seeking. Active scanning refers to semidirected browsing or scanning in likely locations (e.g., medical books in a bookstore, or web pages discussing diabetes). Nondirected scanning involves serendipitous encounter with, and recognizing, a source (e.g., incidentally getting a useful idea from a TV program on how to reduce smoking). Finally, obtaining information by proxy may take place when interacting with information sources through the initiative of another agent: either the information source or some other gatekeeper or intermediaries. For example, an individual interested in the stopping of smoking may receive e-mails from her friend informing about new web pages related to this topic. Alternatively, her friend may have bought a new book on this topic and lends it to the information seeker.

McKenzie's model exemplifies the major tenets of recent studies on information seeking. Information seeking is seen as a highly dynamic and context-dependent activity, drawing on a number of modes that may appear in various orders. The model also exemplifies the growing complexity of ELIS processes (e.g., the ways in which various information resources perceived to be accessible afford ELIS to meet the needs of orienting and problem-specific information).

Information Grounds (Fisher)

Drawing on a series of ethnographic studies, Karen Fisher (née Pettigrew) and her colleagues have developed the concept of information grounds that stands for a spatio-temporally sensitive context of ELIS.^[72] Information grounds may be defined as an environment temporarily created by the behavior of people who have come together to perform a given task, but from which emerges a social atmosphere that fosters the spontaneous and serendipitous sharing of information.^[73] In other words, information grounds stand for an individual's combined perceptions of place, people, and information.^[74,75] Examples of everyday information grounds include medical clinics,

hair salons, bars, clubs, daycare centers, metro buses, bookstores, and libraries.^[17] Grounds of these kinds stand for information-rich places where people indicate an awareness that an appropriate source might be located.

A major characteristic of information grounds is that they can occur anywhere, in any type of temporal setting, and are predicated on the presence of individuals. Second, people gather at information grounds for a primary, instrumental purpose other than information sharing and seeking. Third, social interaction is a primary activity at information grounds, and information flow is a by-product. Fourth, people engage in formal and informal information sharing, and information flow occurs in many directions.^[73] Even though information grounds primarily serve the needs of information sharing, they are also interesting from the viewpoint of ELIS. While people share information, they may also ask specifying questions related to the topic of discussion. Purposive information seeking occurs when someone voluntarily visits an information ground with the purpose of obtaining information.^[71] Nonpurposive information seeking takes place when someone serendipitously encounters information without prior intent.^[73]

In a study focusing on information sharing and seeking at the foot clinic, Pettigrew^[73] found that everyday information flow did not occur solely from nurses to customers, but the latter appeared to be ripe sources of everyday information for the nurses themselves. Multiple persons participated in exchanges and customers shared information while waiting for treatment and afterward. It also appeared that information needs were rarely stated as direct requests but instead emerged subtly as people shared their situations with one another and chit-chatted. This suggests that information sharing may give rise to occasional seeking of information. On the other hand, information may also be shared in the context of information encountering because the information received this way may be passed on to others. Another study explored how new immigrants use coping skills and literacy programs run by Queens Public Library, New York.^[17] Then, the study showed that the immigrants share information in multiple directions often as a part of social interaction and that topics of information seeking could arise quite serendipitously as well as through framing via the literacy program's subjects. Finally, a survey drawing on telephone interviews of residents in East King County, the United States, showed that people favor information grounds by diverse criteria.^[74] However, a common denominator was the opportunity to share common interests or needs, and the feeling as if other people understood their needs, and that these people may be trusted. For example, a health-care facility can provide opportunities to talk with people having similar life experiences.

In the most recent characterization of information grounds, the concept is specified by referring to the people-place-information trichotomy.^[75] More specifically,

information grounds are perceived as a social construct rooted in an individual's combined perceptions of place, people, and information. As the numerous examples of recent studies^[74–76] suggest, the construct of information grounds has not been explicated in a final form; on the contrary, the approach is continually elaborated, both conceptually and empirically.

CONCLUSION

Studies conducted since the 1970s indicate that everyday life information needs and seeking are affected by a number of cognitive, emotional, cultural, and situational factors. ELIS has two major modes. On the one hand, people may seek for orienting information by monitoring daily events through the media; newspapers, television, and the Internet are the most central sources of orienting information. On the other hand, they may seek for problem-specific information. Most frequently, information seeking of this kind is triggered by needs related to health issues, consumer problems, housing, and various kinds of hobbies. To meet these needs, people tend to favor a limited number of easily accessible sources, which have been found useful in previous use contexts.

To a large extent, the major features of ELIS may be condensed into the principles of information seeking proposed by Harris and Dewdney.^[77] Most importantly, these principles suggest that the needs for problem-specific information arise from the situations in which information seekers find themselves; that is, any need for information is situationally based and dependent on a particular context. People also tend to look for the information that is most accessible, sometimes referred to as the principle of the least effort. It also seems that daily information-seeking habits change quite slowly. One of the recurrent findings of ELIS research is people's tendency to favor human sources due to easy access to them and the opportunity to get immediate feedback. However, source preferences may vary in differing information need situations. Depending on their requirements, for example, Wikipedia may be preferred over human sources in cases in which facts about an issue are urgently needed. Since the late 1990s, the Internet has increasingly affected ELIS practices by providing easily accessible sources. Even though the popularity of the networked sources has grown rapidly, it seems that they will complement, rather than replace, more traditional sources and channels.

As the daily information environment becomes more complex and information seeking is affected by an increasing number of contextual factors, there is a need to elaborate the research settings of ELIS. The major challenge is to study contextually the dynamic (situation-bound, sometimes nonlinear and cyclical) processes of ELIS as related to the recurrent patterns of information seeking. More reflective attention is being devoted to the

ways in which the researchers gain access to the everyday life settings of the informants and conceptualize the phenomena of ELIS.^[78] One indication of the progress made in this respect is the elaboration of the theoretical and methodological bases, as exemplified by Chatman's project to develop a social scientific theory of ELIS. Recent examples of promising lines of research include the approaches to information grounds^[72] and information practices.^[38,71] In addition, there is a growing interest in the role of the affective factors, such as emotions and feelings, in the study of health-related^[13,14] and hobby-related information seeking^[21,79] in particular. The study of affective factors is also important because they often make it understandable why people avoid information although it may be readily available.^[14] These developments suggest that the best way to elaborate the picture of ELIS both conceptually and empirically is to thematize it as a contextual everyday practice that incorporates cognitive, affective, and sociocultural elements.^[3,38,67,80] However, ELIS is not rendered meaningful as a separate practice because it is often connected to practices of using and sharing information.

Evidence-Based Practice

Prudence W. Dalrymple

Drexel University College of Computing & Informatics, Philadelphia, Pennsylvania, U.S.A.

Abstract

Evidence-based practice (EBP) is the conscientious, explicit, and judicious use of current best evidence in making decisions. Its aim is to gather, assess, and apply research results that are pertinent to questions that arise in the course of everyday professional practice. Its focus is pragmatic rather than theoretic. Evidence-based library and information practice (EBLIP) comprises a set of principles and practices derived from EBP, primarily the health professions. These principles are described and referenced to examples from the library and information science (LIS) literature. While EBLIP's strongest proponents are found among health sciences librarians, efforts to incorporate evidence into practical decision-making may be found in other sectors in the library and information professions. It is also used as a rationale to encourage enlarging and improving the evidence base of library and information science as a discipline. EBLIP is an international movement of library and information professionals from a number of countries, especially the United Kingdom, Scandinavia, North America, and Australia. As a relatively new movement within the professions, EBP continues to evolve, with changing emphases depending on discipline, region, organization, and topic. Increasing use of qualitative methods and interest in data-driven decisions may affect the role of EBP in LIS.

INTRODUCTION

Evidence-based practice (EBP) is the conscientious, explicit, and judicious use of current best evidence in making decisions. Its aim is to gather, assess, and apply research results that are pertinent to questions that arise in the course of everyday professional practice in a variety of fields. Although EBP encourages the conduct and use of research, it focuses primarily on using research results to solve everyday problems, rather than on undertaking basic research that may or may not have a practical application. EBP is an approach increasingly used in the professions, most notably those in health, education, policy, and social service, in addition to library and information science (LIS). Evidence-based library and information practice (EBLIP) comprises a set of principles and practices derived from EBP in other sectors and espoused by library and information professionals from a number of countries, especially the United Kingdom, Scandinavia, North America, and Australia.

EBLIP evolved during the 1990s as a result of health science librarians' involvement in evidence-based medicine (EBM). As medical librarians participated in the EBM initiatives, they began to explore the feasibility of applying EBM principles to the problems facing a rapidly evolving library world. EBLIP encourages improving the research skills of practicing librarians in order to build a research base that can be applied to improving professional practice in libraries and other information-intensive organizations. As such, its focus is pragmatic rather than theoretical.

While EBLIP's strongest proponents are found among health sciences librarians, efforts to incorporate evidence into practical decision-making may be found in other sectors of the library and information professions. It is also used as a rationale to encourage enlarging and improving the evidence base of the discipline. As a relatively new movement within the professions, EBP continues to evolve, with changing emphases depending on the discipline, region, organization, and topic.

This evolution has benefitted from the biennial, international conferences on EBLIP that began in 1999 and have been held at various locations in Europe, Canada, Australia, and the United States. An open-access, peer-reviewed quarterly journal, *Evidence-Based Library and Information Practice*, was established in 2006 to "provide a forum for librarians and other information professionals to discover research that may contribute to decision-making in professional practice."^[1] The journal's international editorial board includes many of the most prolific writers and strongest advocates for EBLIP. In addition to research reports and commentary, it publishes evidence summaries of previously published research. The journal complements the major text in the field *Evidence-Based Practice for Information Professionals: A Handbook*^[2] and adds to the growing body of literature in the field, much of which has been published in the *Journal of the Medical Library Association*, in *Hypothesis*, the newsletter of the Research Section of the Medical Library Association (MLA), and in *Health Information and Libraries Journal*.

Beginnings in Clinical Medicine

The EBM movement resulted from the observation that clinicians pursued answers to only a few of the information needs they identified during daily practice because they lacked time and access to current, high-quality resources, including critical reviews of the literature that were organized and presented systematically. Increased pressures on clinicians' time due in part to changes in professional practice, and the growth of the biomedical literature, led to concerns that clinicians were making clinical decisions based on tradition and personal inclination rather than on established, scientific evidence. Few of the clinicians' information needs were expressed as actual questions, and even fewer generated searches for answers.^[3] EBM advocates challenge clinicians to become lifelong, self-directed learners, to seek out and apply the results of systematic reviews and meta-analyses, and to practice audit and feedback about their clinical decisions.

By most measures, EBM is a central tenet of clinical practice. EBM is now a part of most medical school curricula, it has been endorsed by the Institute of Medicine, thousands of systematic reviews have been published, and numerous electronic databases and digital devices deliver evidence-based summaries to the clinician at the bedside. Despite this success, EBM has also been criticized as an attempt to make practice formulaic ("cookbook medicine") and to remove professional judgment and values from decision-making. Such criticism prompted Sackett,^[4] the author of a major EBM text, *Clinical Epidemiology*, to reassert the need for a balance between scientific evidence and clinical judgment. Although EBM continues to be critiqued, few dispute the need to collect, filter, synthesize, and apply the available information to clinical practice.^[5,6]

EBP in the Information Professions

Advocates for evidence-based information practice have written extensively to encourage colleagues to adopt evidence-based methods, but at the same time they acknowledge that LIS provides few evidence tools and even fewer incentives for adoption. Not only is the comparatively small research base a barrier to EBP, cultural and communications gaps exist between researchers and practitioners. These gaps, which have been attributed to a myriad of factors—from lack of educational preparation to "semantic impenetrability" and lack of practical utility—have prompted calls to action to address them.^[7] The MLA's research policy *Using Scientific Evidence to Improve Information Practice* (1995) and its successor *The Research Imperative* (2007) envision health information practice whose "core consists of verified scientific evidence, with LIS professionals as creators, managers, and active users of such evidence."^[8,9] The revised policy also links EBP with quality improvement, stating that evidence

[will be] identified, applied, and assessed in a continuous loop of quality improvement with research as the critical underlying construct.^[9] Evidence-based principles are beginning to diffuse through other sectors of library and information practice as indicated by the variety of evidence summaries published in the journal *Evidence-Based Library and Information Practice*.

COMPONENTS OF EVIDENCE-BASED PRACTICE

Though they may be described in a variety of ways and the details may differ according to domain, the components of EBP remain constant. They are

- Formulate the question
- Search for the evidence
- Evaluate the evidence
- Apply the results
- Evaluate the effect

Formulate the Question

In EBP, formulating a question is the ability to state the problem at hand in the form of an answerable question. This step is often preceded by recognizing an information need or "gap" that prompts the question. For example, researchers have analyzed the ways in which physicians decide to pursue answers to questions and studies of the information needs in other domains have found similar patterns.^[10] Once an information need is identified, the need is transformed into an answerable question following a specific pattern. In clinical medicine, the pattern is known as PICO, a mnemonic translated as problem (or patient or population), intervention (prognostic finding or exposure), comparison (with the alternative, including placebo for trials), and outcome (or effect). Examples that apply PICO to clinical questions may be found at many websites such as <https://www.ncbi.nlm.nih.gov/ezproxy2.library.drexel.edu/pmc/?term=3140151>. A template for use when formulating either of two different types of PICO searches in PubMed is available at <http://www.pubmedhh.nlm.nih.gov/nlm/picostudy/pico3.html>. These examples are drawn from clinical medicine, but Booth has taken these models and developed SPICE—setting, perspective, intervention, comparison, and evaluation—an approach that is specific to LIS questions. SPICE stands for facets of a problem that are relevant library and information practice.^[11]

Acknowledging the importance of stating questions in an answerable form has prompted efforts to develop a taxonomy or classification of questions. For example, some basic types of questions in clinical medicine are those having to do with diagnosis, treatment, etiology, prognosis, or prevention, each of which is one facet of a clinical situation.^[10] Similar work has been undertaken with regard to

Table 1 Classification of library questions.

Question from <i>Hypothesis</i> ^a	Revised question	Domain	Potential resources
How can we predict the future usability of a print monograph collection in this electronic environment?	In academic libraries, how do electronic subscriptions affect usage of the print monograph collection?	Collections	LISA, Library Literature, CINAHL
Are students who have been taught information skills more or less likely to continue to further study?	Among students, does being taught information skills by a librarian affect future academic pursuit?	Education	ERIC, MEDLINE, Educational research abstracts, PsycInfo
Is there a way to measure the economic value of the medical library within a hospital?	In hospitals, does having a medical library vs. not having a library impact the hospital's economic viability?	Management	ABI Inform, CBCA, EconLit, MEDLINE
How do we apply outcomes-based evaluation to services in order to realistically demonstrate the impact of what we do?	In presentations to library boards, does the use of outcomes-based evaluation of library services impact upon board members' perception of the importance of library services?	Marketing/Promotion	ABI Inform, CBCA, Library Literature
OPAC vs. library Web sites/databases for e-journal/e-book management—why...?	IN managing e-journal access and retrieval, is using an OPAC vs. a library Web site database for indexing those journals a more user-friendly medium?	Information access and retrieval	LISA, Library Literature, CINAHL, MEDLINE
Can we prove that librarians are more effective at answering reference questions and running literature searches than library technicians?	In reference transactions, do librarians, as compared to library technicians, provide a more complete answer? In literature searching, does a librarian search vs. a library technical search yield higher quality results?	Reference/Enquiries	LISA, Library Literature, CINAHL, MEDLINE

^a <http://www.mlanet.org/p/cm/ld/fid=737&tid=511&sid=647>.

questions in LIS. An illustrative list of questions generated by practicing health science librarians restated as EBL questions and mapped onto six domains of library practice appears in Table 1.^[12] In addition, Eldredge^[13] has proposed three question types—prediction, intervention, and exploration—which can be linked to research designs. Such efforts sharpen questions and help focus on an appropriate research design that will produce useful evidence that can be tapped to solve practical problems.^[13]

Search for Evidence

The next step in EBP is the search for evidence. The purpose of the search for evidence is to enable both researchers and decision-makers to quickly access what is known about a particular topic. In addition to the usual criteria of relevance and recall, an evidence-based search uses special techniques to filter the retrieval, retaining only those items that meet criteria for quality. Indeed, the process of filtering evidence (“quality filtering”) prompted medical librarians to engage in evidence-based activities on behalf of healthcare practitioners.^[14,15] Evidence searching in biomedicine is greatly facilitated by using various “filters” that can restrict retrieval to specific study designs such as randomized controlled trials (RCTs).^[16] These filters limit retrieval to research studies and sort them by research design. When these tools are fully deployed, they constitute an infrastructure of systematic reviews, meta-analyses, guidelines, and statements of best practice that can support evidence-based medical practice.

An infrastructure comparable to that found in medicine does not yet exist in LIS; its modest research base is dispersed across many cognate disciplines such as computer science and technology, education, management, and other social sciences where there are many different approaches to research. While standards for structured abstracts, such as those required by MLA, can simplify the process of retrieving a body of relevant work, they have yet to be universally adopted, and indexing terms do not typically identify study design.^[17,18] Lacking this infrastructure, most LIS searchers employ citation searching, pearl-growing, or snowball strategies enhanced with text words to identify research studies from which evidence can be extracted.

Systematic Review and Evidence Appraisal

The literature search is part of the larger process referred to as a systematic review. A systematic review is a concise summary of the best available evidence that addresses a well-formulated question. It differs from the traditional literature review in that it includes a detailed description of the search strategy, the date(s) of searches, and databases searched (including hand searches) because it is expected that it will be replicated and updated. A systematic review aggregates and synthesizes research findings rated by the strength of their evidence—their validity or freedom from bias, their reliability or trustworthiness; and their applicability or impact. Differences in these dimensions are usually a function of the research design itself,

Table 2 EBL levels of evidence, revised.

Prediction	Intervention	Exploration
Systematic review	Systematic review	Systematic review
Meta-analysis	Meta-analysis	Summing up ^a
Prospective cohort study	RCTs	Comparative study ^b
Retrospective cohort study	Prospective cohort study	Qualitative studies ^c
Survey	Retrospective cohort study	Survey
Case study	Survey	Case study
Expert opinion ^d	Case study	Expert opinion ^d
	Expert opinion ^d	

^{a-d} Eldredge, J. The most relevant and answerable research questions facing the practice of health sciences librarianship. *Hypothesis* 2001 15 (1), 9-14,17. <http://www.mlanet.org/p/cm/ld/fid=737&tid=511&sid=647>.

and because research varies in rigor, each study must be retrieved and reviewed, and the evidence extracted and rated according to a specified protocol. The process of rating the evidence is called evidence appraisal. The results of the appraisal are presented in a format referred to as an evidence table that orders the research according to the strength of its design.

A hierarchy of evidence was first developed in clinical medicine, where the RCT was placed at the top of the hierarchy, reflecting its importance in determining effectiveness of therapeutic interventions. RCTs are rare in LIS; nevertheless, research evidence can be appraised, and several approaches to appraising LIS evidence in LIS have been proposed. Eldredge's^[13] hierarchy of evidence is one of the most well known and resembles the one used in clinical medicine; see Table 2.

In addition to classifying the levels of evidence, critical appraisal of evidence entails detailed analysis of each study selected for inclusion. There are numerous dimensions that can be used; in medicine, for example, there are estimated to be as many as 40 systems used to appraise or grade evidence. These systems incorporate both quantitative and qualitative measures, the former being represented by measures such as statistical power and effect size, while qualitative measures may use designations such as "gold star" or "fatal flaw."^[19]

Because the systematic reviews are fundamental to EBP, bringing them together in a searchable database serves an important purpose. The Cochrane Collaboration, begun in 1993, is the oldest and largest collaborative effort in which hundreds of researchers cooperate to search the medical literature, appraise the evidence, and publish systematic reviews.^[20] While the majority of these are only tangentially related to LIS EBP, they can sometimes be useful; see, for example, the Cochrane Collaboration review on opinion leaders, as well as the collection of Methodology Reviews. In addition to the Cochrane Collaboration, the Cochrane Library collects other databases containing high-quality, independent evidence.

In LIS, Glynn^[21] has developed a critical appraisal tool for LIS that effectively combines questions aimed at internal validity such as research design and execution, with external validity such as whether the evidence is meaningful in a particular setting. Answering these questions can help determine the value of a research report to an organization and problem at hand.

Another evidence-based resource of potential use to LIS is the Campbell Collaboration whose mission is to provide high-quality, sound evidence for practitioners and the public when making decisions about public policy, particularly in education, criminology, social welfare, and other policy areas.^[22]

Meta-Analysis in LIS

Meta-analysis is another important part of EBP in many fields. It is a procedure in which statistical techniques are used to summarize the data of several comparable studies. To conduct a meta-analysis, the study design must be sufficiently detailed and transparent to assure that the studies are comparable. Unfortunately, the research base in LIS lacks standards for reporting research, making it difficult to draw conclusions across multiple studies. Despite these limitations, there are some examples of meta-analysis in LIS research. See, for example, Trahan's^[23] meta-analysis comparing computerized searching to paper-based searching, Chen and Rada's^[24] meta-analysis of hypertext systems, Saxton's^[25] meta-analysis of reference services, and Koufogiannakis and Wiebe's^[26] meta-analysis of methods for teaching information literacy skills.

In order to accomplish the goal of providing a succinct summary of what is known in an area to facilitate and support decision-making, an alternative to meta-analysis known as meta-synthesis has emerged in LIS. Although meta-analysis is usually conducted using quantitative data, the approach described by Light and Pillemer^[27] can produce useful, reliable summaries of research using many different research designs. Their checklist of 10 questions to ask in assessing a review can be particularly useful in LIS because of its applicability to education, policy, and other social science studies. Urquhart describes the technique of meta-synthesis and applies it to information behavior research.^[28] Ke and Cheng examine issues surrounding the application of meta-analysis techniques in LIS, and they conclude that although the body of research in LIS is not currently large enough to support robust meta-analyses or meta-syntheses, the benefits are sufficient to warrant taking steps toward that goal.^[29]

Apply the Results

Applying the results from a systematic review is a goal of EBP, but it is often this step that presents the great barrier. In medicine, the phrase "from bench to bedside" is frequently invoked to illustrate the transition that must take

place for the results of research to be used in patient care. While much has been written about the slow pace with which research is translated into practice, caution must be exercised to avoid exposing patients to therapies whose effectiveness has not been established or whose side effects not fully explored.

In LIS practice, applying evidence obtained from systematic reviews requires an organizational culture that values research and provides incentives and opportunities to practice the basics of EBP. The lack of easily accessible evidence tools and the relatively small research base in LIS contrasts with clinical medicine and creates additional challenges for creating a culture of EBP.

Two recent initiatives have attempted to address this problem. EBLIP advocates conducted Delphi studies in North America and Sweden and developed a research agenda whose objective is to create an evidence base for LIS practice by encouraging a collaborative community of EBP LIS professionals willing to address each of the research questions. This community of practice would undertake both basic research and systematic reviews of existing research to augment the current evidence base supporting LIS practice.^[30]

Another approach advocates building an “evidence base” that can support data-driven decisions. Nicholson proposed aggregating data from multiple sources into a data warehouse that can be used to explore patterns in the data.^[31] While such an approach might lead to “fishing expeditions,” current advances and refinements in data mining techniques are promising. An advantage of using

data is that they reflect the “real world” in all its diversity, rather than an “artificial” or “ideal” world created as part of a research study. This approach—referred to as practice-based evidence—contrasts with EBP and has only very recently been considered. The Association for Research Libraries’ LibQUAL+ suite of services to solicit, track, understand, and act upon users’ opinions of service quality that can be adapted locally may be regarded as an example of practice-based evidence because it uses a systematic approach to data collection and analysis.^[32] Comparing the evidence to the local situation on variables such as user population, budget and funding source, circulation, collection size and characteristics, as well as overall mission and values can help the practitioner assess whether the outcomes presented in the evidence are comparable to the local context and therefore applicable to the problem under consideration.^[33]

Fig. 1 lists examples of LIS research that exemplify evidence-based approaches to solving problems of library and information practice.^[34] To encourage additional work along these lines, EBP researchers and advocates have written extensively on the transfer of research to practice, and the EBLIP literature contains numerous articles that provide practical suggestions for implementing EBP.^[33–39]

Evaluate the Effect

The final step in EBP is evaluation, which includes an assessment of the effort itself and using that assessment in future planning. In this regard, EBLIP benefits from

and uses typical evaluation and assessment techniques. Among them are performance and output measures, quality improvement, audit and feedback, benchmarking, and other performance indicators, to name just a few. Some advocates for EBP have noted that Schön's notion of reflective practice is particularly compatible with the spirit of inquiry implied by the term "reflective practitioner."^[40,41] Through reflective practice, EBLIP professionals engage in a cycle of inquiry, evaluation, reflection, and renewed inquiry that suggests the initial character of EBM—conscientious and judicious, as well as scientific, practice.

SUMMARY

EBLIP is an approach to professional work in which scientific evidence provides the basis for systematic problem-solving. EBLIP encourages both the conduct and the application of practical research in order to improve information practice.

Exhibition Design

Lee H. Skolnick

Dan Marwit

Jo Ann Secor

Lee H. Skolnick Architecture + Design Partnership, New York, New York, U.S.A.

Abstract

Exhibition design, sometimes called exhibit design, is the conceptualizing, planning, and creating of exhibitions—built, spatial environments that communicate with audiences moving through them. As a field of practice, exhibition design has only recently begun gaining definition and standards. Meanwhile, it is flourishing worldwide, as exposition attendance soars, retail environments reinvent themselves, and cultural institutions increasingly appeal to tourism and promote themselves as centers of entertainment, as well as education. Bringing together a constellation of disciplines, exhibitions are designed by teams working through a phased process that translates a script into an immersive experience. Audiences engaging with the experiences interpret them through interactions with their elements, including their architecture, colors, lighting, graphics, artifacts, and media. Design teams continually develop understandings of their audiences as they plan and arrange exhibitions' elements in context. As exhibition design expands in the beginning of the twenty-first century, it turns up new challenges, but as with all design fields, exhibition design views challenges as opportunities.

INTRODUCTION

Exhibition design, sometimes called exhibit design, is the conceptualizing, planning, and creating of exhibitions—built, spatial environments that communicate with audiences moving through them. Broadly, any exhibition can be categorized as either cultural or commercial, but more commonalities than differences are shared across this border. Really it is the permutation of many particularities, including content, intention, size, setting, duration, expected audience, and experience type that determine what an exhibition can be and how it gets designed.

In the world of museums, there are those that use artifacts, archival images, and text to document events for visitors with preexisting knowledge, and those that engage wide audiences in explorations of phenomena, ideas, and themes through interactivity and play. Among visitor centers, many attract year-round tourism to civic icons, while others showcase corporate accomplishments to employees and invited guests only. From trade shows to international expos, independent environments compete on the same floor for the attention of industry associates or the general public, whose interests in a new product, brand, or philosophy can translate into investment. Any of these exhibitions can be open for a matter of days or decades, and designing them requires attending to their distinct natures appropriately.

All exhibitions are designed by teams. To be sure, the exhibition designer's contribution is the core of the work, as the final product is inevitably a physical environment that functions and directs people in intended ways.

However, in order to create a total design, subteams, who together determine the story that guides the design, give the design its shape and tone, plan and create vital elements, and build and install the actual components.

Because the field of exhibition design is quite young, few exhibition designers, or design team members for that matter, have come to their titles through a course of exhibition design study. Rather, most approached the field through one of several avenues: designers through architecture, industrial design, commercial package design, and furniture design; and other team members through education, anthropology, and creative writing. Each of these has some bearing in exhibition design, but also requires designers and team members to think beyond their fields and work cooperatively, as none address all of an exhibition's needs.

Like all processes, the exhibition design process follows a sequence of phases, moving from concept design to schematic design, into design development, and finally fabrication documents and fabrication and installation. Each of these phases, often referred to differently by different designers, can be further delineated into smaller steps, and are typically completed in a reiterative fashion. Culminating in the production of documents that signify milestones and transitions, the phases keep team members working toward common goals in a shared time frame, and enable ongoing assessment of a project's progress that is captured and presented. A truer exploration of exhibition design would require quite a bit more space, and a few exceptional books have been written for that purpose, including David Dernie's *Exhibition Design*, Larry

Klein's *Exhibits: Planning and Design*, Kathleen McLean's *Planning for People in Museum Exhibitions*, and Jan Lorenc, Lee Skolnick, and Craig Berger's *What Is Exhibition Design?* Also, because the field is one that is constantly reinventing itself, a richer understanding of exhibition design can be had with some continual study. Periodicals, like *Exhibitor* and *Exhibitionist* would encourage this, as would attendance at conferences, like the annual American Association of Museums conference. Finally, the best way to discover the burgeoning field of exhibition design is to visit exhibitions. Each one is so different from the next that comparisons made between them would awaken any curious person to the craft invested in them.

A last note: The background shared by the writers is mostly of cultural exhibition design in American settings. Much has been done to reach outside this limited scope, but the history of exhibition design in Europe, and the excitingly expanding field in both Europe and Asia are topics that easily warrant entire articles all their own. Exhibition design has unquestionably become a worldwide phenomenon, and its ubiquitous trends are reaching into other fields everywhere. While this entry is reliable in its overview of exhibition design, there is much more to explore, and readers are enthusiastically encouraged to do so.

HISTORY

The origins of exhibition design are at once self-evident and evasive. Humans naturally arrange objects for the communication of particular statements. We do it in our homes and other environments. Arguably, creating exhibitions is innate, and people have been doing it since the day they realized they could manipulate their surroundings.^[1]

European Roots

Appearing in biblical passages and Roman history, trade fairs are as ancient as trade, itself, but trade fair exhibitions as they appear today have their roots in European history, as do exhibitions in museums.^[2,3] The first of the known major fairs, which has continued since at least 1165, was the *Leipziger Messe* in Leipzig, Germany.^[4] Meanwhile, the origins of museums has been traced to the European Age of Enlightenment, when proponents of the Age's interest in making sense of the world, cultivated the first natural history collections in *wunderkammern*, or *cabinets of curiosity*.^[5] Essentially the province of royalty and the Church, several *wunderkammern* grew into renowned institutions, the *Modern Museums of Copenhagen* and the *Louvre* among them.^[6,7] While most *wunderkammern*, overflowing with collectibles and exotic rarities, were meant to impress onlookers with their owner's prestige, a number showed early signs of design,

like thematically arranged floor plans and inclusion of interpretive text.^[8,9]

Transition to Planned Experiences

In 1786, Charles Willson Peale brought museums to the public, opening *Peale's American Museum* in Philadelphia, PA.^[10] While Peale's museum set a new precedent for curation, that of collecting and displaying culturally representative objects for the benefit of its visitors, its displays followed from the *wunderkammern*, voluminous, and somewhat indiscriminate. This style would hold sway until the *Museum of Modern Art* in New York shifted the paradigm in the 1940s with minimally displayed arrangements of "empathetic" pieces.^[11]

Meanwhile, in the commercial sphere, exhibition design took a leap forward in 1851 with *The Great Exhibition of the Works of Industry of All Nations*.^[11] Planned by Prince Albert and Henry Cole of England, the *Great Exhibition* was the first truly international exhibition. Bringing 13,000 exhibitors and 6,000,000 visitors together under the roof of Joseph Paxton's *Crystal Palace*, the *Great Exhibition* set the standard for future expositions, and led to the formation of formal oversight organizations, like the *Bureau International des Expositions*. In the coming years, expos grew increasingly impressive, with permanent structures designed by reputable engineers and architects, including the *Eiffel Tower* by Gustave Eiffel for the 1889 *Universal Exhibition*, the current *Museum of Science and Industry* for the 1893 *World's Columbian Exposition* in Chicago, and the *German Pavillion* by Ludwig Mies van der Rohe for the 1929 *Barcelona International Exposition*.^[12-14] Also in the nineteenth century's latter half, department stores began appearing worldwide. Their competition for an emerging spending culture led them to install exhibitions of power and branding in their entrances and main floors.^[15] *Wanamakers* in Philadelphia built a *Grand Court* with a commanding bald eagle as its dome.

Toward a Contemporary Vision

In 1939, expositions moved into a new era. With the *New York World's Fair's* theme *Tomorrow's World*, expos began addressing humanity and cultural issues, rather than technology and inventions.^[16] Amusement rides and stage set architecture set the scene for designers to begin creating entire environments at fairs, one more exciting than the last. Following this course, the 1964 New York World's Fair marked a seminal moment with 140 full pavilions, four designed by the Walt Disney Corporation, and one by Charles and Ray Eames. Disney, equipped with a team of *Imagineers* and a list of *Mickey's Ten Commandments*, had by this time opened Disneyland in California, 1955.^[17] The Eames team, with their chairs that both broke and set the mold, had already opened a

number of exhibitions, including the *American Pavilion* in Moscow, 1959, and *Mathematica* in 1961, which remained open at the Los Angeles Museum of Science and Industry until 1998, and has since been duplicated at several institutions.^[18]

Also at this time, many larger American institutions, like the National Museum of American History and the Field Museum of Natural History, created exhibition planning departments, shifting power away from curators. These departments created *blockbuster* exhibitions, like the Field's *Tut*, that drew enormous crowds and set a new pace for museum exhibition design. In this atmosphere, museums began rethinking the purpose of exhibitions and the structures of the departments responsible for them. Michael Spock of the field museum advocated for including into design teams educators and content developers who could translate scholarship into stories for general audiences. Frank Oppenheimer of the Exploratorium in San Francisco challenged the nature of museum exhibitions altogether, populating them with interactive experiences from which visitors derived their own interpretations. A series of workshops at the Field in 1982, sponsored by the W. K. Kellogg Foundation demonstrated the effectiveness of a team approach to designing museum exhibitions, an approach that has been adopted and adapted by museums far and wide.^[19]

Today, at the onset of a new century, fairs, trade shows, and expos around the world draw attendance rates rivaling those of the Olympic Games.^[20] Museums and visitor centers find themselves competing for expanding tourism and audiences looking for entertainment as much as education.^[21] Design firms are increasingly contracted to plan both cultural and commercial exhibitions, and the resulting cross-pollination is benefiting both arenas.^[22] Undoubtedly, exhibition design is flourishing, and work by firms in Japan, Korea, and other Asian nations is inspiring exciting movement worldwide.^[22]

ELEMENTS

All exhibitions are compositions of space, architectural elements, materials, graphics, color, lighting, and acoustics. Most also include objects, artifacts and images, and increasingly media components. The available variety of materials and methods is remarkably vast, and expanding rapidly with technological advances. The possible uses of them in shaping immersive, transcendent experiences for visitors are as many as the needs of each individual exhibition, and those needs are governed by the exhibition's narrative and context.^[23]

Narrative

The narrative, also variably known as the script, messaging, or storyline, is in plain terms what the exhibition is

about. It is developed from a body of knowledge, a corporate philosophy, a set of ideas, concepts or messages or a promotion of a brand, and subsequently completed with additional research as necessary. Structuring the information to be presented in the exhibition, the narrative also suggests how the information should be accessed and interpreted. Thus, it sets the foundation for decisions about how the environment will communicate with its visitors.^[24]

Context: Physical and Cultural

An exhibition set inside a building not yet constructed, allows opportunities to work with an architect in tailoring important features to the exhibition's needs. These can include circulation, ceiling heights, natural lighting, and access to mechanical, electrical, and plumbing systems. However, more often designers plan exhibitions for existing buildings, working either with or around the context's features.^[23] Meanwhile, the situation of an exhibition in a surrounding culture determines who might attend it, and how it might be interpreted by attendees, as well as by press outlets, schools, various communities, and other groups. Depending on its reach, an exhibition's cultural context can require wrestling with every detail of its narrative and design, especially in the handling of controversial topics.

Space

Space is the volumetric area that the exhibition organizes and thematically conditions. It is usually contained by structural walls, a floor and a ceiling within an interior, or imaginarily assigned within a larger interior, as with the space designated to a trade show booth. An exhibition can also be outside, but its space is still limited and its organization is still in the designer's hands. To organize space, designers consider aesthetic and experiential properties, including scale, proportion and balance, site line, and visitor flow, among others. All together, these properties choreograph the positioning of exhibition elements in relationship to one another.^[25]

Architectural Elements

Architectural elements are those that are constructed to define the exhibition's space and display its feature elements. Walls built to partition spaces, ramps pitched to steer visitor flow, platforms created to elevate experiences, and built forms inserted for interpretive effect are just a few examples. In interactive exhibitions, these elements also serve a second purpose of housing and protecting mechanics and audio/visual and computer equipment. Furniture built for comfort or as part of an experience, and cases that contain collection items or display products are also architectural elements that have design qualities all their own, and whose appearance in the space further defines it.

Materials: Construction and Finishes

Materials are used to build the exhibition's architecture, enable the mounting and presentation of other elements, and evoke particular associations and sensations. Construction materials, often hidden from view, are usually generic, like wood, steel, drywall, and fiberboard. Finishes are materials that exhibition visitors see, or that support the other elements that visitors see, like affixed graphics and painted colors. Traditionally, these materials have been finished woods and different grades of glass, as in the display cases of object-based exhibitions.^[26] Recently, technological advances have opened an expansive repertoire of materials to designers, including ranges of new metals, plastics, and laminates, making it easier to evoke emotions and interpret information and themes through shape and texture. New materials also aid in placing graphics and colors in desired locations, as their properties make them lightweight and receptive to paint and adhesives.^[27]

Graphics

Graphics are two-dimensional designs applied to surfaces. In some instances, they are painted directly onto finishes. More often, they are created with computer software, printed on substrates with adhesive backings, and applied to surfaces prior to their installation. Featuring text, diagrams, and images, graphics are used to deliver information and suggest context. Composed of typefaces, color palettes, patterns, and illustrations, graphics are also used to set an exhibition's tone, and unify its interpretive and navigational systems. As computer and printing technology advances, graphics are increasingly designed to cover large exhibition surfaces, like entire walls, floors, and ceilings.^[28,29]

Color, Lighting, and Acoustics

Color, lighting, and acoustics can be grouped together as environmentally interpretive tools. They are often the most effective tools in transporting visitors to believable places, or immersing them in convincing ideas. Colors conjure emotions and psychological associations, especially in juxtaposition or cooperation with one another. Lighting both makes things visible and sets a range of moods. Acoustics control sound, dampening it in some places, and allowing it to escalate in others. Together, these elements make a richly interpretive exhibition experience possible, and also strongly influence its feeling.^[30]

Objects, Artifacts, and Images

Objects, artifacts, and images are often a client or institution's reason for creating an exhibition, in the first place. In many cases, the display of one or more of these elements is intended to create a brand by which an institution or

business becomes known to the public. They can be small enough to require a microscope, or large enough to fit groups of people inside; sensitive enough to warrant controlled conditions, or best experienced through touch and manipulation. Exhibition designers create environments that both highlight these elements as attractions and storytelling elements, and protect them as necessary.

Media

Media in exhibitions commonly refers to on-screen media, which includes film, video, and interactive virtual experiences. Increasingly, media is becoming a standard expectation. A handful of exhibitions have even been designed with media as their central themes, or with media pieces serving as pinnacle experiences. Media has become highly sophisticated, able to respond to users in surprising ways, and to perform ever more complex functions. Fully immersive media experiences are now not only possible, but are even becoming commonplace. Balancing these powerful experiences with the rest of an exhibition has become an important challenge for designers.

PROCESS

From start to finish, the creation of an exhibition can take several weeks to several years, depending on its size and the complications of its content, context, and physical requirements. Certainly, every designer has his or her own approach to bringing an exhibition from nonexistent to open to the public, but all create through a process that advances through a series of work phases.^[31] Referring to the phases, designers often use different terminology, but commonly they are known in sequence as concept, schematic, design development, fabrication documents, and fabrication and installation.

From here, the process appears step-by-step and direct. However, the progression of an exhibition's design is rarely so simple and linear. Rather, designers work in what is called a reiterative fashion, meaning that within each phase iterations of designs are completed, reviewed, and revised until satisfactory. On a macro level, whole phases can be reiterated until complete; on a micro level, single drawings or written descriptions can cycle in their own reiterative processes. Further emphasizing the process' reiterative direction, exhibition designers typically allow for returns to previous process phases either to complete unfinished steps, or to revise designs as new information and insights emerge. In mapping a process at a project's outset, designers try to plan ahead for these motions, doing their best to keep to schedule and within budget.

Throughout the exhibition design process, a succession of document sets, or packages is produced. Each set signifies a benchmark, simultaneously presenting the culmination of

the designer's work up to that point, and establishing the new foundation from which the work will continue. Titled after the process phases they complete, the document sets are typically known as concept, schematic, design development, and fabrication documents. In the fabrication and installation phase, there are no benchmark documents, as the culmination of this phase is the opening of the exhibition itself.

Concept

The concept phase marks the initiation of an exhibition design project. Its primary goal is the establishment of the exhibition's foundations, and its principal work is characterized by research, brainstorming, and exploration. To determine what the exhibition will be about, initial research into its topic is conducted, structured into a hierarchy or framework, and developed into a preliminary script. The script determines the exhibition's perspective or approach to the topic, and with it in place, the exhibition's general look, feel, and function begin to bloom through a series of brainstorming sessions. From the sessions, designers make explorations, sketching architecture, and exhibit ideas that could appropriately translate the script into an experience.

The concept document set can include:

- Concept outline, exhibition criteria, preliminary script.
- Sketches or diagrams of the whole space and its components.
- Analyses of projected attendance and circulation.
- Initial rough budget projections.
- Preliminary schedule.
- Suggestions of graphic style, copy style, and object and artifact placements.
- Suggestions for marketing and outreach.

Schematic

During the schematic phase, the approved concept is used to create a preliminary design for the entire exhibition. The goal of the schematic phase is to identify the exhibition's components and make them imaginable, while leaving room for their details to be developed and debated. Extending from the preceding phase, script writing, brainstorming, and exploration continue until the concept is fully fleshed out, and a design for the entire exhibition can be proposed and discussed. Making this possible, designers begin seriously assessing the physical context in which the exhibition will be installed, as well as the host's resources for marketing, outreach, and staffing.

The schematic document set can include:

- Finished preliminary script.
- Revised project budget and schedule.

- Floor plans.
- Sketches of vignettes and component elevations.
- Foam core spatial models and mock-ups, or photographs of them.

Design Development

While the body of the exhibition has been made imaginable by the schematic designs, its details still need to be elaborated. The goal of the design development phase is to specify the exhibition's details. The thrust of the phase is in making definite choices about the tangible things that will compose the three-dimensional environment, including materials, colors, graphics, text, equipment, lighting schemes, A/V scripts, and computer software. The decision-based character of design development shifts the focus of the exhibition design process from imagining possibilities to making the chosen possibilities work.

The design development document set can include:

- Plan, elevation, and sectional drawings of all exhibition components.
- Written descriptions of all exhibition components.
- Preliminary *schedules*, lists of materials, graphics, A/V equipment, and hardware and descriptions of their uses.
- Updated project budget and schedule.

Fabrication Documents

In the fabrication documents phase, the decisions made in the design development phase are incorporated into a set of technical drawings and specifications. The goal of the fabrication documents phase is twofold: first, to produce documents so highly detailed that they can serve as instructions for fabricating the exhibition; second, to identify a fabricator. Every detail of the exhibition, down to its literal nuts and bolts, is specified, recorded in *schedules* and indicated in hard-line drawings. Once this is done, designers open a competitive bidding process, unless a trusted fabricator is already known. Designers also open bidding for other contractors, including media producers, graphics producers, and copywriters, if they have not yet been chosen.

The fabrication document set can include:

- Hard-line, dimensioned plan, elevation, section, and "exploded" drawings of every exhibition component with close-ups of important details and specifications of materials and hardware.
- Finalized *schedules*.
- Plans for lighting, electricity, A/V connections, mechanics, and plumbing.
- Final project budget and schedule.

Fabrication and Installation

The final phase, fabrication and installation, takes the exhibition from drawing and study to actuality. The goal of this phase is a successful opening, and to get there takes meticulous decisions on behalf of clients. First, the fabrication drawings are delivered to the chosen fabricator. The fabricator reviews them and returns them as *shop drawings* with suggestions of necessary, and sometimes creative revisions. The designer then reviews the revisions, and either approves them or makes further suggestions. This back and forth shuttling continues until the fabricator is confident he or she can build precisely what the designer wants. Ensuring the fabrication meets the design's intents, the designer makes frequent visits to the fabricator's shop during this phase, as well as to the studios of other contractors. Present at the exhibition's installation, designers watch over details to the very end.

No documents are delivered during the fabrication and installation phase. The culmination of the phase is the exhibition's opening.

UNDERSTANDING AUDIENCE

Throughout the process, designers strive to understand their audience as best they can, and get ideas from them about how to better the exhibition's design.^[32] To reiterate the point: Any exhibition is a medium for communication. Its very purpose for being built rests on the fact that people will visit it.^[33] Who those people are—children, adults, scholars, the general public, etc.—determines the verbal, visual, and experiential language most appropriate for the dialog.^[34–36] Cultivating an understanding of the audience not only encourages an exhibition's success, it recognizes its responsibility. To this end, many designers conduct formal studies of their audiences at different phases of the process. Often, contracted evaluators are hired to perform these studies more systematically and objectively.^[37]

Initial Understanding: Front-End

During the concept phase, or even prior to it, many designers conduct *front-end evaluations*. Learning what an audience already knows and feels about an exhibition's topic can help set the parameters of its script and influence its possible presentation and tone. Considering an audience's abilities and learning styles helps produce exhibits that are suitable for them. Certainly, fair generalizations about an exhibition's intended audience can be made with demographics, learning theories, and past precedents, but many designers prefer to “meet” their audiences, or representatives thereof, through formal studies, such as questionnaires, focus groups, and interviews.

Informed Understanding: Formative

Arguably, the most useful evaluation, *formative evaluation*, can be conducted in the schematic design phase, when it becomes possible to gauge audience reactions accurately before moving into the latter decision-making phases.^[38] By providing them with drawings, designers can ask evaluation participants direct questions about a fairly imaginable exhibition. By presenting them with foam-core mock-ups, designers can observe participants' interactions with their designs, often adjusting the mock-ups to test various possibilities. Follow-up interviews and questionnaires provide insights into what audiences are deriving from their experiences. Results and recommendations from these tests are used to finalize schematic plans and prepare for making determined design decisions in the next phase.

Specific Understanding: Prototyping

During the design development phase, concerns about the operations of particular exhibit components arise. Because the level of detail is so specific in this phase, it becomes possible to build full-scale *prototypes* of these components. If the budget allows, designers can try variations of actual materials and mechanics until the component works exactly as intended. Including audiences in prototype testing can be extremely informative, as very reliable observations can be made from their engagements with and reactions to the exhibition.

Final Understanding: Summative

No better reaction to an exhibition can be gauged than that of an actual audience in the actual space. Often, designers add a postopening phase to the exhibition design process during which modifications can be made to exhibit components that for all their planning do not result as intended. Formal studies of audiences during this phase, known as *summative evaluations*, time and observe interactions and behaviors, and gather audience responses through interviews. The findings of these studies can often point to simple solutions to apparent issues, or lessons for the next project.

DESIGNERS AND DESIGN TEAMS

Because by their nature, exhibitions are cross-disciplinary experiences, they are designed by teams. Depending on the size of the exhibition, teams can be comprised of individuals, or entire departments. In many cases, coordination of the players' contributions, and assurance of their mutual understanding of a shared process are as crucial for a project's success as any individual's talent.

The assembling of a team can be the task of a lead team member, or a manager who serves a more supervisory role. In most design firms and museum exhibition departments, team members are chosen from full-time staff. Meanwhile, it is not uncommon for firms and departments to complete teams by hiring freelance workers. In some cases, teams are formed solely for the project at hand. In still other cases, teams can include a core team surrounded by peripheral ones, made up of hired experts, volunteer advisors, interested community members, and so on. In any instance, when assembling a team, the goal is to select compatible team members, whose talents and interests match the needs of the exhibition, some of which will unfold as the project develops.^[39,40]

Making decisions together, and communicating in general, are critical tasks for exhibition design teams, especially those working on large projects that take years to complete. Many models exist for structuring teams and enabling their collective efforts.^[41] They range on a spectrum from linear hierarchies, with one chief decision maker, to egalitarian committees that strive for consensus.

Similar to teams working in other fields of design and communications media, exhibition design teams generally divide their responsibilities into at least two sides (not a technical term, but one commonly used), one to handle the development of the story, *content*, and the other to handle its telling, *design*. Often, teams also include a third side, *project management*, to coordinate the actions of the whole team and supervise the production of the entire project.

Within their sides, individual team members work toward common goals, but it is through the collaboration between sides that an exhibition is fully designed. Both content and design bring their work to the table, and management ensures that the story and its telling remain within the project's feasibility. Thus, some permeability between sides is usually important for best practice. A team whose members respect each other's roles, but can think in each other's terms is the most likely to succeed with greatest ease.

Content Team

Responsible for the story itself, team members on the content side can include curators, educators, exhibit developers, interpretive planners, content developers, content coordinators, researchers, and writers. Collectively, their role is to cultivate the ideas, topics, and information to be conveyed in the exhibition, and articulate them in a manner that visitors will be able to grasp. The process of doing so typically follows a reiterative course of accumulating, editing and arranging knowledge that relies on research, organization, analysis, association, and story-writing skills.

In the design of exhibitions that are rich in objects and artifacts, content team members also maintain knowledge

of available collections and external sources. Sometimes, entire stories are constructed around the showing of a single item. Other times, it is through categorizing items and selecting the most totemic ones that a story emerges. Knowing what is obtainable, and understanding how the inclusion and omission of particular objects and artifacts will affect a story is the job of content team members.

Once a compelling story has been developed, the collective role of content team members becomes that of ensuring that the design expresses it, and that the expression is appropriate to the intended visitors. Often, this calls for responses to evaluation findings, and additional research and development to inform the details of the story as its translation manifests.

Design Team

Determining how to tell the story, the design side of the team can comprise a variety of designers from various disciplines, including graphics, media, lighting, and acoustics, all of whose work is coordinated by a lead exhibit designer, typically also supervising the efforts of junior exhibit designers. Oftentimes, draftspeople, model makers, illustrators, and other talents are added to the design side to aid its diverse disciplines. All together, design team members give the exhibition dimensionality that people can enter, navigate, use, and share.

Beginning with rough sketches, designers' transition to drawings, and finally hard-line drawings as they reiteratively conceptualize, plan, and detail the visual and experiential communication of the content. Inevitably, the act of drawing reveals problems in the exhibition's functionality and challenges to its proper expressions. Solving these problems is part of designing exhibits, and doing so often requires invention. Most designers welcome such detours, viewing their pursuit as opportunities to make their designs unique and successful.

As the exhibition develops, the various designers' work affects each other. Graphics influence the exhibition's look, light reflects on graphic surfaces in unexpected ways, audio from media transforms acoustic spaces. Meanwhile, each of the design contributions carries material concerns. Lighting grids need to be suspended and electrically wired, graphics need substrates that adhere to surfaces, and acoustics call for very specific finishes. Each of these is researched, sized, and specified by the design side, and the responsibility for all of it fitting together, both conceptually and tangibly, resides with design team members.

Project Management Side

Responsible for the exhibition's opening on time and within budget, the management side of the team usually includes one project manager. Typically the liaison between the team and the project's client, the project

manager drafts a scope and a schedule and budget for its completion, and communicates progress, delays, and changes between parties. Because the project manager remains aware of time, money, and the client's concerns, design teams frequently look to him or her to remind them of parameters on their creativity. While this can be a politically sensitive position, it is a critical one. Not only does it help the team accomplish the job properly, but it also protects team members from investing beyond the project's bounds, keeping them from overworking and making sure they'll be available when needed for the next project.

Because bringing an exhibition to its fruition involves the weaving together of so many efforts over time, coordination is the project manager's principal and constant task.^[42] With the many team members working independently on their ends of the project, the project manager resides at the center, keeping everyone apprised of each other's progress, and helping maintain the team's camaraderie and morale. At times, this can require great tact, as any one team member's progress can easily influence changes, or even pose difficulties in that of another.

CONCLUSION: CONTEMPORARY TRENDS AND CHALLENGES

The current state of exhibition design is an effervescent one. Still relatively young, and certainly younger than the museums and expos it services, its movement toward becoming a formalized field has accelerated in recent years, but its standards of practice have yet to be codified. Only a handful of design schools teach it as a subject, and only in rare instances is it offered as a full course or major.^[43–45] Professionals of various types are filling its positions, and their writings about their own experiences are some of the first. Meanwhile, exhibition design is growing by leaps and bounds, and gaining momentum around the world, as cultural institutions, corporations, businesses, public awareness campaigns, city governments, and more call upon the unique mode of communication that only exhibitions can offer.

The Next Big Way to Present the Next Big Thing

Over the last few decades, attendance rates at international expos have skyrocketed into the tens of millions. Meanwhile, casinos like *New York, New York*, and retail chains like *Apple*, *Niketown*, and *IKEA* have realized the power of reshaping their stores into total, experiential environments.^[46] In both arenas, the goal of communication is to present the next big thing, be it a product, brand, lifestyle, or philosophy. Competition in the commercial sphere has become intense and fast-paced, and designers are constantly looking for the next big way to present the next big thing. As a result, in many ways, commercial exhibition

design has become a proving ground for many new technologies, materials, and strategies.^[47]

More and more frequently, these new technologies, materials, and strategies are also being incorporated into cultural exhibition design. One possible reason is that most exhibition design firms work in both arenas, often supplementing their abilities in the cultural sphere with earnings from the commercial sphere. Another is the recently emergent phenomenon of in-house teams collaborating with contracted designers, who give shape to expertly researched content in institutions whose staff knows the audience quite well.

New Perspectives of Interpretation

In years past, knowing an audience was less valued by cultural institutions who viewed themselves as having a more authoritative role. The shift toward gauging visitor expectations and interests, often through focus groups, surveys, and other tools familiar to the commercial sector, is a recent one that is swiftly setting a new paradigm. Responding to visitors, cultural institutions have learned how to maintain and expand their public reach. Enabling this response, designers increasingly plan exhibitions that are more able to communicate with particular audiences. To do so, many design teams have added educators to their talent and educational theory to their tool kits.^[48] Not limited to cultural exhibitions, commercial designers have also begun to consider experiential learning, constructivism, multiple intelligence theory, theories of intrinsic motivation, and others as helpful guides in creating communicative environments.^[49–52]

Universal Access

Along the same lines, a recent phenomenon is the requirement of planning for people with disabilities. While designers have always taken this into consideration, as one goal has always been to reach as many people as possible, allowing for universal access has in many places become enforceable by law. In the United States, title III, section 36.101 of the Americans with Disabilities Act (ADA) of 1990 “prohibits discrimination on the basis of disability. . . and requires places of public accommodation and commercial facilities to be designed. . . in compliance with the accessibility standards established” by the ADA.^[53,54] As stated in explicit terms, exhibition designers, like the designers of any nonresidential facility, are now legally obligated to plan environments that do not exclude physically impaired people. The ramifications of this are enormous, as are the opportunities. On one hand a suite of new constraints are imposed; on the other hand, implementing standards like the ADA's positions designers to revolutionize communities by creating wholly inclusive environments.

New Narratives

The trend in museums to respond to visitors' interests has engendered the rise in popularity of issue-based exhibitions, made possible by a popular push away from object-based exhibitions and towards concept-based ones. As race, death, health, fear, and other conceptual explorations become crowd-draws for museums, exhibitions are changing shape to suit a very different genre of narrative. Designers increasingly plan environments that embody questions and journeys, rather than simply representations of topical times and places.^[55]

New Technology

One undeniable force that has transformed exhibition design in just the last few years is digital technology and the hurrying pace of its advances. Computers are now small enough and powerful enough to easily be hidden from view, while providing incredibly rich experiences. Video and screen-based interactivity can deliver massive amounts of self-discovered information without consuming much space. The temptation to fill an exhibition with digital experiences is a pressing one for many designers, and often something close to that is requested by a client.

Meanwhile, computers' shrinking dimensions and escalating abilities are placing more of them in more people's homes and pockets, equipping people with rich experiences that require no environmental contexts. The need to create digital experiences that are unique, or more sophisticated than what is available to consumers, has become demanding for exhibition designers. Likewise, the challenge of designing real environments equally or more exciting than virtual ones has become an actual pressure.^[56]

One emerging solution is the design of digital experiences that are integrated into exhibition environments.^[57] As technologies like motion tracking and multitouch flat screens become more accessible, this solution has grown more viable. Another emerging solution is the invention of new technologies and varieties of interfaces. Speaking to both solutions, a new industry is burgeoning.^[58–60] Digital designers contracting with exhibition designers are gaining popularity, often winning bids for jobs as collaborative teams.

New Technology Backstage

The influence of technology's innovations is also revolutionizing exhibition design behind the scenes. Software applications, like *Photoshop*, *Illustrator*, *AutoCAD*, *3D Studio Max*, *Sketch Up*, *Revit*, and *Vectorworks*, have nearly rendered obsolete traditional design tools, like compasses, shape palettes, drafting tables, and pencils. At the same time, the Internet has become an indispensable resource for content developers and researchers, as well as

a location for idea-exchange forums hosted by design communities, like the Association of Science-Technology Center's *Exhibit Files* Web site and blog.^[61] E-mail and FTP's have expedited communications between teams and clients, and also made it possible to easily collaborate across oceans. The effect of this sweeping change of tools is not only immeasurable, but also hardly complete.

Accounting for Sustainability

All exhibitions are made of materials whose processing and transportation extracts natural resources and emits greenhouse gasses.^[23,62] Lighting, video projections, and other electrically powered elements drain large amounts of energy and produce pollution when sources of power are fossil-fuel-burning power plants. Publicly supported regulations and institutions like the World Green Building Council are setting standards for designers to follow, and making those standards achievable by helping grow an economy for them. As these concerns swell in the public conscience, designers have an opportunity to serve as vanguards by creating sustainable exhibitions visited by millions of people.

Looking Forward

In any field of design, the root of the practice is in presenting information and emotion in new and more effective fashions. Responsively, designers view the challenges of the day as abundances of promising opportunities. As today's exhibition designers plan environments that engage people in experiences in compelling new ways, they raise the field from its youth to its fruition. As they stay aware of trends and plan one step ahead of them, they raise the bar.

Facet Analysis [*ELIS Classic*]

Douglas J. Foskett

University of London, London, U.K.

Abstract

The brothers Foskett, Anthony and Douglas, have both made major contributions to the theory and practice of subject analysis and description. Here, Douglas Foskett explains facet analysis, a vital technique in the development of both classification schemes and thesauri. Foskett himself created faceted classification schemes for specific disciplines, drawing from the philosophy of the great Indian classificationist, S.R. Ranganathan.

—*ELIS Classic*, from 1972

INTRODUCTION

The term “facet analysis” was first introduced into discussions of bibliographical classification by S.R. Ranganathan to denote the technique of separating the various elements of complex subjects in relation to a set of abstract fundamental concepts. The *Colon Classification*^[1,2] is the only example of a general classification scheme covering the whole of knowledge that is entirely based on facet principles, but many other special schemes have been made using this technique, and a simple account of the methodology was presented to the Washington Conference on Scientific Information in 1958.^[3] Ranganathan has expounded the theory and practice in many writings; the basic theoretical work is the *Prolegomena to Library Classification*, of which the third edition has appeared,^[4] and advances in his research are regularly reported in the Indian journal *Library Science with a Slant to Documentation*. Perhaps the best introductions to his work, however, remain a paper to the British Society for Visiting Scientists given in 1948^[5] and a monograph prepared for the Library Research Monograph series of the University Library in Copenhagen.^[6] In the latter, Ranganathan defines facet analysis as

the mental process by which the possible trains of characteristics which can form the basis of classification of a subject are enumerated and the exact measure in which the attributes concerned are incident in the subject are determined. Facets are inherent in the subject.

B.C. Vickery, in a contribution for the Classification Research Group (q.v.), writes that “a faceted classification is a schedule of standard terms to be used in the subject description of documents,”^[7] and he has shown the relation of facet analysis to the general analysis of information in his article “Analysis of Information” (q.v.).

BACKGROUND

Classification, both the word and the process, begins with the Greeks, who used it for the purpose of forming definitions of *things*. For Plato, to know things meant to place them in their correct class according to their permanent, ideal form, or essence, and Aristotle in his *Logic* analyzed in detail the processes by which one could identify things by starting with a group or class of objects, and then eliminating all members of the class except the one aimed at, by enumerating specific properties not possessed by the others. Thus, by starting with the class, or *genus*, one could arrive at the individual, or *species* by enumerating properties that stated differences between one species and another. This form of division is still best seen in the so-called “classificatory sciences,” especially Zoology and Botany, in which the genera may be divided into the individual animals and plants; we may start with a class such as vertebrates, and by the division on the basis of successive characteristics we arrive at a chain of sub-classes such as mammals—(primates)—anthropoid—apes (chimpanzees). This sort of classificatory process proved of great value for the development of these sciences, and the description of individual species is still of value today. We can, for example, profit by the description of individual libraries and information services, studying their similarities and differences to arrive at a more general theory of what these organizations should be like under ideal conditions.

One of the most important aspects of the achievement of Melvil Dewey in the decimal classification was to show how the use of the decimal fraction notation could provide a systematic sequence of subjects, which mirrored this form of classification and which would therefore arrange books or other documents, such as index cards, in a pattern that would be readily recognized by the specialist in any subject as corresponding to the way in which he thought

about his subject. But the literature of specialist subjects in all fields, including the “classificatory sciences,” is no longer mainly a literature of description of individual species, as it was to a great extent in the nineteenth century. The field of knowledge has advanced in complexity, and specialist writing now consists much more of the discussion of the relations and interconnections subsisting between entities than of mere descriptions of the entities themselves. We need, therefore, a scheme of categories of terms which will do more than imitate the genus–species relation.

Dewey had already realized that this problem existed and provided for a certain element of synthesis as well as analysis in his schedules. He knew that any subject might in principle at least be subdivided geographically, but rather than enumerating a complete geographical table under each subject, he introduced the technique of adding on the schedule from the class 900, inserting a zero in front of the 9 to indicate that this was the point at which a new aspect (or facet) of the subject was about to be introduced. This process was carried much further by the International Federation for Documentation (q.v.) in its revisions of the universal decimal classification, and in his bibliographic classification, H.E. Bliss used the systematic auxiliary schedules to carry out the classificatory process which he called “composite specification.”

All of these schemes, however, failed to provide a systematic basis for the use of synthesis in classifying a complex subject, and the inevitable result is a mixture of subjects in the same array, arrived at by applying different characteristics of division in one series instead of one at a time. In the Dewey decimal classification, for example, we find arrays like this:

370	Education
370.1	Theory
370.7	Study
370.71	Meetings
370.72	Conferences
370.73	Teachers’ Colleges
370.732	Courses and programs

It is obvious that “Courses and programs” are not *species* (i.e., special types) of “Teachers’ Colleges,” and that “Teachers’ Colleges” themselves are not *species* of “Study”; on the other hand, “Conferences” might reasonably be called *species* of “Meetings.” The true nature of the various hierarchies are not demonstrated; all terms are enumerated as if the genus–species relation were the only one, and all subdivisions were examples of it.

The aim of the writer of a document is to study phenomena in the round; he observes all the aspects of a given entity—its appearance, its structure, and the interrelationships and interactions that exist between one entity or group of entities and another. He tries to describe a

universe that is dynamic and not static, and this means that it is not sufficient to rely any longer on schemes of classification that attempt to force all types of relation into a pattern that actually exhibits only the generic relation.

Perhaps the simplest way of illustrating this is to consider a technology. The aim of a technology is to take some material or object, such as a piece of steel or aluminum, or a measure of some substance, and then to work on it to change it into something else. We apply an activity or operation to the entity or raw material and turn it into another entity—the end product. Thus, we have two types of entity terms (raw material and end product) and the operation terms (which might be stamping, extruding, heating, and so on).

The purpose of facet analysis is to provide a framework within which all these various types of terms can be accommodated, together with rules for their combination as required by the literature. It uses the term “analysis” to replace the older term “division” because division implies the breaking up of a single entity, but analysis has a wider connotation and may be applied to the study of complexes as well as of entities. A facet can be said to be all the classes produced when a subject is divided by one and only one characteristic. Classes in a scheme of classification are represented by words or terms, and a facet is therefore a list of terms in which each term stands in the same relation to the subject of which it is a part. A facet may consist of entity terms, such as elements in chemistry, or crops in agriculture; forms of entities, such as solid, liquid, gas; operations made on entities, such as combustion, forging, harvesting; tools for operations, such as presses, x-rays for therapy, microscopes; states of being, such as health and disease.

In applying facet analysis to a subject, the first step is to examine a representative sample of the literature and enumerate the subject of each article, book, or abstract. It soon becomes clear that the terms encountered may be grouped together in sets according to their relation to the subject and to each other, that they represent, in fact, the various aspects of the subject, each of which can be studied apart from the others, at least conceptually, even though in practice it may be impossible to separate them into groups of static entities apart from the phenomena in which they are observed. Consider the following subjects from journal articles in the field of occupational safety and health:

The lighting of underground roadways in coal mines.
 The protection of workers against ionizing radiations.
 The examination and testing of dust masks.
 Dermatologic aspects of the chromate problem.
 Guarding of machines used by blind workers.
 Registration of accidents in nuclear reactors.

From these, and other subjects like them, one can easily deduce the following facets:

Classes of workers (blind, etc.)
 Industries (where hazards exist: coal mines, reactors)
 Sources of hazards (things causing danger: dust, chromates, radiation, machines)
 Accidents and diseases (results of hazards: dermatitis)
 Prevention (masks, guarding)
 Administration (registration, etc.)

It can readily be seen now that the basic difference between a faceted classification and a merely enumerative one is that here the terms are itemized as elementary terms and are not combined into complexes for insertion in the schedules of the scheme. For classifying documents, terms are used mainly in a postcoordinate manner because they are not precoordinated in the schedules, except insofar as a generic hierarchy may still legitimately be inserted into a facet. In a faceted scheme for education, we can find, in the “Educand” facet, the following sequence:

Exceptional children
 Handicapped children
 Physically handicapped children
 Blind
 Deaf
 Brain-injured

Terms signifying other aspects, such as curriculum subjects or teaching methods, will likewise be enumerated only as elementary terms in separate facets, and any combination of elementary terms that may appear in the literature can therefore be catered for as it arises.

One particular kind of facet is called a differential facet. This is a facet of a class in which the terms are secondary to another facet and may differ according to the term to which they are attached in the primary facet. If we look at the subject “Food Technology,” for example, we can enumerate the various groups of foodstuffs in the primary facet: meat products, dairy products, vegetable products, and so on; in the “Process or Operations” facet, the types of process vary according to the food group. The operations for processing dairy or cereal products are different from those used in processing meat or fish products. Thus, although the name of the facet may be a general term such as “Process” or “Operation,” the individual terms in the facet will fall into several separate groups depending on the term in the product facet to which they apply.

To find a sound theoretical basis for the choice and sequence of facets in a scheme, Ranganathan advanced the solution of relating facets to a set of fundamental abstract notions, which he called time, space, energy, matter, and personality. Every facet of a basic class is regarded as a concrete manifestation of one of these. The time facet is for chronological division, and the space facet for geographical division; these are clear and are to be found in virtually every classification scheme. Energy and matter, illustrated in a technology by raw material and process, are

not so easily identified in some other subjects in the social sciences and humanities, for example. Personality, if interpreted as the end product in a technology, or the educand in education, can be seen to be a recognizable entity with an identity that is unique and clearly separable from other entities, but it has certainly caused more difficulty and controversy than any of Ranganathan’s other fundamental categories. Nevertheless, for him it is the most important of the categories, because it is the personality facet that contains the terms that give the class itself its own identity in the field of knowledge.

It is clear that many compound subjects found in the literature will display more than three basic facets, excluding space and time, which normally will only appear once. To meet this situation, Ranganathan introduced the idea of levels and rounds of facets. In Class I, Botany, of the Colon Classification, the individual plants are classified into natural groups as the First Level Personality; for example:

1	Cryptogamia
2	Thallophyta
22	Algae, seaweeds
23	Fungi
237	Basidiomycete
2375	Mushroom
5	Phanerogamia
7	Monocotyledon
8	Dicotyledon

But parts of plants are also personality terms and are placed as Second Level Personality in the same facet as the plants themselves (i.e., before the appearance of any other facet). For example:

1	Basic and regional
13	Root
14	Stem
16	Flower

The two levels of the personality facet are joined by a comma. Thus, the notation symbol for the plant gentian is I 8516, and the symbol for the flower of the gentian is I 8516,16; the preceding comma enables us to distinguish between the 16, which indicates the division gentian of the group *Dicotyledons*, and the 16, which indicates the part flower and which could be added in the same way to the symbol for any other plant.

Rounds of facets are necessary because each type of term may appear more than once in a compound subject. In a technology, we may very well find the tool specified which carries out a certain operation on a certain raw material to produce a certain end product. A tool is an entity and in the context of the manufacture of the tool it would appear as the primary personality. But it is not

primary in the context of using it for the production of another entity; that entity is the primary personality because that is the entity on which primary attention is focused. Similarly, in the class agriculture, fertilizers are regarded as personality terms, but agriculture is not concerned with the production but with the use of fertilizers. The crop is the primary focus of attention in agriculture and is, therefore, the First Round Personality facet. This facet is followed by an operation or energy facet that contains, among others, these terms:

1	Soil
2	Manure
4	Disease
7	Harvesting

The symbol that introduces an energy term is the colon. Thus, the notation for the crop turnip is J 332, and the symbol for the subject, the manuring of turnips is J 332 : 2. After this, the different kinds of fertilizer that may be used for the manuring of turnips are listed as the Second Round Personality facet. Ranganathan has postulated that there are no subdivisions (second levels) of any energy term, so that Second Round Personality terms do not require any indicating symbol but may run straight on after the symbol for the appropriate energy term:

1	Green manure
2	Farm
4	Fertilizer
41	Nitrogenous
42	Phosphatic

The combined symbol for “the use of phosphates in the cultivation of turnips” is therefore J 332 : 242. A full explanation of these devices has been given by Ranganathan in his Rutgers seminar.^[2]

There is no doubt at all that these fundamental categories are easy to identify in some subjects and particularly in science and technology. They have been used with success as a checking device for subject analysis in relation to the decimal classification in the *British National Bibliography* and in relation to an alphabetical index in the *British Technology Index* (q.v.). It is very useful to have in mind some generalized idea of the structure of subjects when either constructing a classification scheme or when classifying documents. Unfortunately, it is not so easy to see the application in the Social Sciences or the Humanities, and the Classification Research Group and other research workers, particularly on the Continent, have tended to follow a more pragmatic approach and, while using facet analysis, to give

the facets a more precise name limited to the subject field being classified. Examples are given by Vickery in another Rutgers seminar;^[8] whether the technique is allied to the notion of fundamental categories or not, however, it certainly provides the most powerful tool yet devised for the analysis of subjects, both for classifying documents and for search strategy in information retrieval.

There are some who seem to think that the arrival of computers has relieved librarians and information officers of the necessity to perform this operation and that all that will be required in the future is for clerical workers to file text into the machine in the natural language of authors and file requests in the natural language of users, and take for granted these two varieties of natural language will match. Operating experience (with perhaps the exception of stores that are so small as to be insignificant for real-life purposes) shows the contrary; and most machine-based systems now are provided with some form of vocabulary control, usually in the form of a “thesaurus.” Although many of the early thesauri were no more than what had hitherto been called by librarians “subject headings lists,” it has lately been realized that the efficiency of these lists, both for input and search strategy, is greatly increased if there is, in addition to the alphabetical list, a second list of the same terms arranged into categories. In one case these have been called “facets,”^[9] and the superiority of this Barhydt-Schmidt thesaurus of educational terms over the alphabetic thesaurus issued by the U.S. Office of Education is so marked that the latter has included in its second edition a rough and not very ready approximation to a set of categories called “descriptor groups.”

The most effective combinations to date have been those produced by D. Soergel for a chemical company in Germany and by Jean Aitchison as a new version of the faceted classification scheme compiled for the English Electric Co. and described in Vickery’s Rutgers seminar.^[8] The new version has been called a Thesaurofacet,^[10] and Jean Aitchison has also published a simplified account of the technique.^[11] She has used the faceted structure to present a pattern of the most basic relationships subsisting between the phenomena denoted by the terms in the system and has complemented this by introducing all the other manifold relationships that may appear in the actual literature into the thesaurus, which now acts as both an entry vocabulary to the system for precisely named terms and a detailed and highly structured alphabetical index to the faceted classification. The characteristic features of each technique have been exploited to achieve a very complete pair of structured vocabularies with the maximum of economy: relations that are more satisfactorily displayed in one list are not repeated in the other. The two lists are linked by the notation of the classification scheme.

CONCLUSION

Information science, unlike information theory, is concerned with meaning and communication as well as with the transfer of messages. Communication means conveying the meaning of a message so that the recipient is able to fit it into the pattern of ideas that already exists in his mind. Library systems should be so formed that they can do this; they should attempt to correspond with the structure of reality, which writers attempt to describe so that the system of terms in the writer's mind may be inserted into a matrix that can be used in turn as a pattern for matching with the system of terms in a user's mind.

It should be a lattice system able to form the same relations as those existing in the infinitely varied phenomena of Nature, and not a single hierarchy, however "logical," such as those on which the traditional library classification schemes are based. Facet analysis provides such a lattice system. It corresponds to the way in which specialists think about their subjects and has, therefore, a vital role to play in modern library and information services, including those that make use of the most sophisticated of machines.

Faceted Application of Subject Terminology (FAST)

Eric R. Childress

Diane Vizine-Goetz

OCLC, Dublin, Ohio, U.S.A.

Abstract

FAST (faceted application of subject terminology) is a faceted subject heading vocabulary derived chiefly from the Library of Congress Subject Headings (LCSH), a widely-used subject heading system published and maintained by the Library of Congress (LC). A controlled vocabulary with simple application rules and a design well suited to Linked Data applications, FAST has been developed through a multi-year collaboration of OCLC Research and the Library of Congress with advice from the library community. OCLC is responsible for the ongoing development of FAST.

INTRODUCTION

Faceted application of subject terminology (FAST) is an enumerative, faceted subject heading vocabulary that consists of eight categories of terms, or facets, that cover key attributes of information resources (topics, persons, organizations, events, places, titles of works, time, and form/genre). Derived chiefly from the Library of Congress Subject Headings (LCSH), FAST retains the rich vocabulary of LCSH and benefits greatly from the ongoing development of LC-controlled vocabularies. In contrast to LCSH, which provides authority records for main headings and subdivisions but not all valid combinations allowed by LCSH application rules, all authorized FAST headings, except FAST chronological headings, are established in an authority file. The FAST authority file is available in multiple representations including MACHine-Readable Cataloging (MARC) and Resource Description Framework (RDF). Individual FAST authority records can also be accessed through a web interface and as Linked Data.

FAST was developed to meet the need for a general-use subject vocabulary that is easy to learn, apply, and control. As a controlled vocabulary that consists of eight independent but complementary facets, FAST is designed to work well in a Linked Data environment and in information systems that support post-coordinate retrieval and faceted navigation. Ongoing development of FAST includes synchronizing with LCSH, providing tools for users, and enhancing FAST records with supplemental information.

BACKGROUND

History of the FAST Project

The origins of the FAST project can be traced to work with Dublin Core (DC) features in the Cooperative Online

Resource Catalog (CORC) service (1998–2002). CORC included a novel metadata editor that allowed input and modification of metadata in both DC and MARC views^[1] and the ability to easily shift between DC and MARC views by virtue of a sophisticated crosswalk.^[2] OCLC staff members and CORC participants valued this feature, but it revealed difficulties in mapping LCSH between DC and MARC. The chief issue was that valid LCSH topical strings can include multiple aspects (e.g., topic, place, time, form) in the same MARC tag, but in DC each aspect typically belongs to different DC elements. The machine logic required to properly map parts of LCSH constructed headings between MARC and DC was judged impractical, and in a best-case scenario would only have allowed a one-way mapping.

With this issue in mind, OCLC Research staff members began exploring the possibility of faceting LCSH into a new vocabulary. If the project was successful, LCSH's rich vocabulary would be recast to be more amenable to use in contexts where metadata was expressed in DC or other non-MARC formats or in workflows that relied on staff unfamiliar with LCSH application rules.^[3,4]

Influences

The release of the report, *Subject Data in the Metadata Record*, in 1999 further inspired the FAST team to persist in its efforts to simplify and adapt LCSH. The report included the following recommendations:

Schemes for supplying subject data should, to the fullest possible extent:

- *be simple and easy to apply and comprehend;*
- *be intuitive so that sophisticated training in subject indexing and classification, while highly desirable, is not required in order to implement them;*

- *be scalable for implementation from the simplest to the most sophisticated;*
- *be logical so that it requires the least effort to understand and to implement; and,*
- *be appropriate to the specific discipline and subject, and to the domain of implementation such as libraries, museums, archives, information services, the scientific community, and personal knowledge management.*^[5]

These objectives resonated with the general goals of the FAST project. While never expressly adopted by the team, the subcommittee's recommendations have influenced the team in its decision-making over the course of the project.

FAST AND LCSH

FAST is derived from LCSH and benefits significantly from LCSH's strengths as a large, general vocabulary maintained by LC. As a widely adopted vocabulary, LCSH covers all subject areas, imposes synonym and homograph control, includes many cross-references, and is updated regularly by LC. LCSH has been added to tens of millions of metadata descriptions including nearly 100 million in WorldCat. The FAST authority file is built chiefly from three sources: 1) the LCSH authority file, 2) millions of constructed LCSH present in WorldCat, and 3) the NACO Authority file. Constructed headings, representing authorized combinations of LCSH, serve as literary warrant and effectively focus FAST on the universe of things represented in library collections. As LCSH evolves and improves, FAST is adapted to reflect the changes and enhancements.

The individual terms in the FAST vocabulary are divided into seven subject facets and a form/genre facet.^[6] The headings in the subject facets are used to describe what a work is *about*; the terms in form/genre facet are used to represent what a resource or document *is*, for example, an encyclopedia. The facets are named

- Topical
- Geographic name (place)
- Corporate name (organization)
- Personal name
- Title of work
- Event name
- Chronological (date or time period)
- Form/genre

FAST is intended for use in post-coordinate retrieval; however, FAST does contain multiple concept headings. They appear as compound phrases (e.g., *agriculture and state*), prepositional phrases (e.g., *conservation of natural resources*), and as main heading/subdivision combinations (e.g., *natural gas—conservation*).^[7] Headings

such as these reflect the vocabulary of LCSH and will be familiar to users of LC Subject Headings. Where FAST differs from LCSH is in the rules for combining subdivisions. In FAST, all terms in the heading must come from the same facet. Topical headings can only be combined with topical subdivisions, geographic names with other geographic names. A main heading may not be combined with a subdivision from another facet.

FACETS

Topical Headings

FAST topical headings look very similar to established topical headings in LCSH. Topical headings in FAST are made up of topical main headings and main heading/subdivision combinations that have been used in WorldCat bibliographic records, including topical heading/free-floating subdivision combinations and expansions of multiple headings.^[8] Topical headings are the majority of subject headings used in cataloging.^[9] The following are examples of FAST topical headings:

AIDS (disease)
 Church work with youth
 Cities and towns
 Murder—investigation
 Political science
 Roads—design and construction
 Roads—design and construction—safety measures
 Travel
 Water—pollution
 Women—employment
 Women—employment reentry—public opinion

Geographic Names

The FAST geographic name facet contains place names that are the subject of a work, including names of countries and political or administrative divisions within countries, states, cities, and towns. These names are referred to as jurisdictional names. FAST also includes names for natural features and man-made structures, referred to as nonjurisdictional names. Jurisdictional names are derived primarily from the NACO Authority File, and nonjurisdictional names are derived from LCSH.

Jurisdictional names

China
 France
 Texas
 Wales

Nonjurisdictional names

Arizona—Grand Canyon
 Maritime Provinces
 North America
 Pacific Ocean

In FAST, the structure of geographic names is hierarchal and is based on the *MARC Code List for Geographic Areas*.^[10] The heading begins with the first-level name and may contain two additional levels. First-level names are normally names of countries or larger areas except for Australia, Canada, Great Britain, and the United States. For these areas, second-level entities such as provinces and states are treated as first level names (Texas rather than United States—Texas). Additional geographic entities are given special treatment in FAST including extinct cities, bodies of water, and extraterrestrial bodies.^[11] The following are examples of geographic name headings:

First-level names

Atlantic Ocean
 North America
 Texas

Second-level names

Arizona—Grand Canyon
 Atlantic Ocean—Baltic Sea
 England—London
 France—Provence

Third-level name

California—Los Angeles—Sunset Boulevard
 England—London—Chelsea
 New York (State)—New York—Central Park

Personal Names, Corporate Names, and Title of Work

Personal and corporate names and titles of works are established as FAST headings. They are based on headings in the NACO Authority File. Only the names that have been used at least once as a subject in a WorldCat bibliographic record are established in FAST.

Personal Names

Personal name headings in FAST look much like established headings in the NACO Authority File. They may not be combined with subdivisions from other facets, but contain one or more following elements:

- Personal name (surname and/or forename)
- Numeration
- Words associated with a name
- More complete form of the name
- Date(s)

The following are examples of personal name headings:

Austen, Jane, 1775–1817
 Beyoncé, 1981–
 Downey, Robert, Jr., 1965–
 Francis, Pope, 1936–
 Marie Antoinette, Queen, consort of Louis XVI, King of France, 1755–1793
 Milne, A. A. (Alan Alexander), 1882–1956
 Sting (Musician)

Corporate Names

Corporate name headings are established for corporate bodies, which include public and private organizations, associations, institutions, governments, government agencies, commercial firms, nonprofit enterprises, and religious bodies. Corporate name headings may not be combined with subdivisions from other facets, but they may contain one or more elements for subordinate units combined with the main heading. The following are examples of FAST corporate name headings:

Canada. Parliament. House of Commons
 eBay (Firm)
 European Union
 Metropolitan Museum of Art (New York, N.Y.)
 Peace Corps (U.S.)
 United States National Aeronautics and Space Administration
 World Bank

Title of Work

A FAST heading for title of work is the title of a work used as subject heading. For example, a critical work about *Pride and Prejudice* by Jane Austen would have the FAST heading *Pride and Prejudice* (Austen, Jane) as a subject heading. Headings for titles fall into three main categories: anonymous works, works of known personal authorship, and works from corporate bodies.^[12] FAST headings for titles begin with the title followed by the name of the creator except for anonymous works. Dates of authors/creators are not included unless the dates are necessary to avoid conflicts. The following are examples of titles of works:

Beowulf
 Dame aux camélias (Play) (Dumas, Alexandre, 1824–1895)
 Declaration of Independence (United States)
 Divina commedia (Dante Alighieri)
 Pride and Prejudice (Austen, Jane)
 Romeo and Juliet (Shakespeare, William)
 Trois mousquetaires (Dumas, Alexandre, 1802–1870)
 Winnie-the-Pooh (Milne, A. A.)

Qualifiers are added to titles to identify the type of work or distinguish between works with the same title, for example:

- Romeo and Juliet (Choreographic work : Balanchine and Nijinska)
- Romeo and Juliet (Motion picture : 1936)
- Romeo and Juliet (Motion picture : 1968)

Event Names

In FAST, an event is defined as something that occurs during a particular time period. An event may be recurring or a single occurrence. FAST event headings are derived from LCSH topical and geographic headings and chronological subdivisions, conference names and meeting names in the NACO Authority File, and subject fields in WorldCat bibliographic records. There are four main types of event headings:

1. Military conflicts—headings for wars, battles, and sieges, etc., include the place and date as the qualifier unless it is redundant.
 - Cuban Missile Crisis (1962)
 - Revolution (France : 1789–1799)
 - Soviet Occupation of Afghanistan (1979–1989)
 - World War (1914–1918)
2. Conferences and meetings
 - G8 Summit
 - Paris Peace Conference (1919–1920)
 - South by Southwest Music and Media Conference
3. Sporting events
 - Stanley Cup (Hockey)
 - British Open (Golf tournament)
 - World Cup (Rugby football)
4. Other types of events, for example, strikes, festivals, natural disasters
 - Burning Man (Festival)
 - Fukushima Nuclear Disaster (Japan : 2011)
 - Indian Ocean Tsunami (2004)

Only event names that have been used at least once as a subject in a WorldCat bibliographic record are established in FAST.

Chronological

FAST chronological headings contain either a single date or date range consisting of a beginning date and an ending date. Either the beginning date or the ending date can be open. An individual date usually consists of only a year. The chronological facet is not controlled but relies on syntax rules for formulating headings.^[13] The following

are examples of four types of commonly occurring chronological headings:

1. Single date
 - 1975
 - 1941 (December 7)
2. Beginning date
 - Since 2000
3. Ending date
 - To 1900
4. Date range
 - 2003–2011

Form and Genre Headings

FAST form and genre headings are derived from LCSH. Form and genre terms are used to describe what a work *is* in contrast to what a work is *about*. Form headings are used to indicate form of presentation or arrangement, intended audience, or physical medium. Genre headings indicate categories of works characterized by plot, theme, setting, etc. The following are examples of form and genre headings:

- Atlases
- Catalogs
- Fiction
- Guidebooks
- Periodicals
- Photographs
- Scores

APPLICATION RULES

When applying any subject vocabulary, catalogers and indexers must also choose between summarization and depth indexing. A cataloger employing summarization will apply subject terms based the overall theme or content of the resource. A metadata specialist using the depth indexing approach will attempt to represent all significant aspects of a work. Either method is appropriate for use with FAST.

As the first step in assigning FAST, a cataloger or other user applies personal judgment to determine which attributes (e.g., topic, geographic name, event, etc.) are primary for the resource being described, and whether the resource should also be categorized as a particular form or genre. The next step is to categorize the concepts by FAST facets and then select the appropriate heading from the FAST authority file. The FAST database contains all

valid main headings and main heading/subdivision combinations and selected tracings for variant and related headings. If no FAST heading for a particular topic has been established, then either a broader heading or multiple headings may be assigned to represent the topic. It is common practice in subject cataloging to use the most specific term available in the vocabulary to describe the resource. For example, for a resource about mice, the FAST heading, Mice, should be used instead of the headings, Rodents or Mammals.

DEVELOPMENT AND MAINTENANCE OF FAST

Generating FAST Headings

FAST headings are generated from 1) established headings in the LCSH Authority File, 2) headings extracted from WorldCat bibliographic records, and 3) name headings in the NACO Name Authority File. The initial steps in the development of FAST were to algorithmically facet and validate all unique LCSH topical and geographic headings in WorldCat records. The validity of a heading from WorldCat was calculated based on frequency of use, source of cataloging, and various validation tables built from LC subject cataloging guidelines. A MARC 21 authority record was then created for each validated heading. As part of the generation and updating of FAST authority records, metrics for frequency of use of a given heading are generated and included in the FAST authority record. Table 1 provides a mapping of the facets to the appropriate fields in MARC21 bibliographic and authority records.

The FAST authority file is available for download^[14] as a single file or by individual facet. In a particular application, some facets may not be required, or one or more of the facets may be used with another controlled vocabulary. The following are examples of a FAST topical authority record and a FAST geographic authority record, respectively:

```
LDR00000cz a2200037n 45 0
001 fst01099527
003 OCoLC
```

Table 1 Mapping of FAST facets to MARC 21 fields

FAST geographic name records include latitude, longitude, and geographic feature type when available. The sources of this information are LCSH and NACO authority records, and the GeoNames database. Software was created to match FAST geographic names to entries in the GeoNames database as part of the development of FAST.

Maintaining the FAST Authority File

Each month new and changed LCSH and new main heading/subdivision combinations from WorldCat are incorporated into the FAST Authority file. Headings from WorldCat must meet thresholds for literary warrant. Most of the updates are algorithmically determined; however, the more complicated mappings may require manual editing or review. When a valid FAST heading changes, its previously authorized form is maintained in a tracing field (MARC 4xx \$wnne). Authority records for all previously valid headings are marked as obsolete (record status changed to “x” and retained in the FAST authority file.

TOOLS AND IMPLEMENTATIONS

Tools

Several tools are available from OCLC Research to help users understand and apply FAST.

FASTConverter

FASTConverter is a web application that converts LCSH headings to FAST headings.^[15] This tool helps users become familiar with FAST and see the differences between LCSH and FAST. When a bibliographic record contains valid LCSH, it is possible to programmatically generate the corresponding set of FAST headings. Each subject heading is processed separately to create one or more FAST headings. The resulting FAST headings are then sorted and duplicate headings are removed. Conversion of sample sets of records allows for the evaluation of FAST as a subject cataloging system.

A central component of the FAST project is computer code that efficiently converts LCSH to FAST headings in bibliographic files. FASTConverter provides access to the conversion process for manually entered headings or for small sets of bibliographic records. LCSH headings can be entered as text, with conversion results displayed as plain text; or, MARC21 format bibliographic files can be uploaded for conversion. A link to the converted file is returned. Conversion files are limited to 50,000 bytes, or approximately 500 records. The following is an example of a set of LCSH headings before and after conversion to FAST:

LCSH before conversion

Personal name headings

Lacks, Henrietta, 1920-1951—Health

Lacks, Henrietta, 1920–1951

Topical headings

Cancer—Patients—Virginia—Biography

African American women—History

Human experimentation in medicine—United States—History

HeLa cells

Cancer—Research

Cell culture

Medical ethics

FAST headings after conversion

Personal name headings

Lacks, Henrietta, 1920–1951

Topical headings

African American women

Cancer—Patients

Cancer—Research

Cell culture

Health

HeLa cells

Human experimentation in medicine

Medical ethics

Geographic names

United States

Virginia

Form/genre headings

Biography

History

The same headings, as they would appear in a MARC 21 bibliographic record, are shown later. Each FAST heading includes a link to its corresponding FAST authority record in subfield \$0. The inclusion of FAST authority record numbers in subfield \$0 facilitates the automated validation and maintenance of FAST headings in bibliographic records.

Headings before conversion

600 10\$a Lacks, Henrietta, \$d 1920–1951 \$x Health.

650 #0\$a Cancer \$x Patients \$z Virginia \$v Biography.

650 #0\$a African American women \$x History.

assignFAST

The assignFAST service provides autosuggest-style searching of the FAST subject heading database. The

feature is accessible through a web-based user interface and through an application programming interface (API).^[16] The user interface is ideal for day-to-day cataloging tasks. When a user of the web application starts typing, suggested authorized headings and variant headings are displayed. When a user selects either type of heading, the application presents a correctly formatted heading that can be copied into a cataloging interface. The API allows software developers to integrate the feature into another service or application.^[17] The API enables easy selection of controlled FAST headings and can eliminate cut and paste operations.

searchFAST

SearchFAST is a full-featured search interface to the FAST authority file^[18] that simplifies the process of heading selection. The user interface provides a search box, brief results list, and full view of a selected record on a single page. To increase searching accuracy, the application provides several indexes and the ability to restrict the results to a desired facet. Search results are ranked by usage, which positions the most likely candidate headings near the top of the results list. Search results can also be sorted alphabetically and in facet order. The user interface includes an autosuggest feature that makes the selection process even easier.

Implementations

WorldCat and FAST

Beginning in September 2013—in response to interest and requests from member libraries and to make OCLC's use of FAST easier to implement—OCLC began systematically adding FAST headings to WorldCat bibliographic records.^[19] The records affected are those with LCSH assigned, and the routines are applied only to records that are attributed as being English-language-of-cataloging. The FAST enrichments are presented to users of WorldCat.org (a discovery interface) and Connexion (a cataloging interface) when users view an individual record, and also appear in Linked Data serializations of WorldCat that OCLC supports.

Metadata editing tools and FAST

OCLC WorldShare Record Manager provides a convenient means of adding FAST headings for users that are using the “text” view in the editor. This feature was made available as part of Record Manager in 2014.^[20]

MarcEdit, a popular open source metadata editing tool maintained by Terry Reese, has a “Generate FAST Headings” tool feature. This feature was added to MarcEdit in October 2013 and makes use of the assignFAST API.^[21]

The BIBFRAME Scribe prototype by Zepheira demonstrates how to catalog materials in a native BIBFRAME

serialization. Scribe includes a search-and-FAST component in its editing toolkit.^[22]

Backstage LibraryWorks provides a FAST validation service to its customers. The service can determine whether a given heading in a bibliographic record is a valid FAST heading.^[23]

Agencies using FAST

Based on a study^[24] by OCLC and other sources, at the writing of this entry a small number of institutions are known to be using FAST routinely. These include

- Bodleian Libraries, University of Oxford (UK)
- Chronicling Illinois & The Papers of Abraham Lincoln projects (US)
- Cornell University Libraries (US)^[25]
- Databib.org (US)
- National Library of New Zealand (New Zealand)
- OCLC (US)
- RMIT Publishing (Australia)
- University of North Dakota (US)

Common applications include the use of FAST in metadata for digital materials (Oxford, Chronicling Illinois, Papers of Abraham Lincoln, University of North Dakota), journal articles (National Library of New Zealand, RMIT), datasets (Databib), and inside discovery tools (Cornell, OCLC).

RESEARCH

FAST Linked Data

During the initial phases of the FAST project, OCLC made a copy of the FAST authority file available up request, in MARC 21 authority format, to a small number of parties. As OCLC began releasing publicly accessible data sets, the FAST team pursued publishing FAST for open access.

In late 2011 with the support of LC, OCLC made the FAST authority file available as a data set under the ODC-By open license.^[26] Formats offered include RDF, MARC 21, and MARC XML. FAST incorporates links to corresponding LCSH authorities. In addition, many of the geographic headings have links to the GeoNames geographic database^[27] and personal names, corporate names, and titles of works records link to the VIAF (Virtual International Authority File) database^[28] hosted by OCLC. FAST as linked data (expressed as schema.org) also appears in many worldcat.org linked data representations of WorldCat bibliographic data. An example of a FAST authority record as RDF is shown next:

```

OCLC Research Prototypes

OCLC Research develops prototypes and demonstrations systems to test ideas and processes. FAST appears in several OCLC Research prototypes. The following are some examples:

mapFAST

mapFAST is a mashup of FAST geographic and event authority data and Google Maps. The prototype is

designed to provide map-based access to bibliographic records.^[29] Mobile versions are also available.

WorldCat Identities

WorldCat Identities provides a characterization for every name in WorldCat. It includes a list of works by and about the identity, a FAST tag cloud of places, topics, etc., closely related to works by and about the person, links to coauthors, and more.^[30]

Classify

Classify is an Functional Requirements for Bibliographic Records (FRBR)-based prototype designed to support the assignment of classification numbers and subject headings for books, DVDs, CDs, and other types of materials. FAST headings are used for the subject index and on the summary display.^[31]

CONCLUSION

FAST, with its simple application rules, modular design, and tools for automated application and maintenance, is well positioned to meet the needs of catalogers and indexers challenged to provide efficient subject access to growing numbers of diverse resources. However, the future of FAST as a subject access tool will depend on the continued updating and development of the vocabulary, application of FAST to content, and a growing partnership with the community of FAST users.

ACKNOWLEDGMENTS

We acknowledge the careful reading and feedback from their fellow FAST Team members, Rick Bennett and Kerre Kammerer (both of OCLC Research). We also thank Edward T. O'Neill (OCLC Research, retired), Lynn El-Hoshy (Library of Congress, retired) and the late Lois Mai Chan (University of Kentucky, retired) for their indirect contributions as we have drawn upon their work, thinking, and writing as inspiration while preparing this entry.

Federal Electronic Information in the United States

Carol D. Doyle

*Government Documents Department and Map Library, California State University, Fresno,
California, U.S.A.*

Abstract

The dissemination of federal information in electronic form, and in particular the use of the Internet, offer the opportunity to provide more timely, convenient, and widespread access to government information resources. However, identifying and locating needed government information can be difficult and frustrating for users attempting to navigate the fragmented and complex federal information landscape. This fragmentation is seen in the overwhelming number of federal Web sites that lack central coordination, even within a specific organizational hierarchy (e.g., departmental or legislative). It also appears in the varying media and formats in which the information may be offered and in the use of partnerships and privatization to distribute government information. Navigation is made more difficult by the fact that government information offered via the Web frequently changes location or apparently entirely disappears. The existence of multiple comprehensive locators, GPO Access, FedWorld, and the GILS, all established at the direction of Congress, and the Executive Branch's FirstGov, illustrates the lack of an overall strategy for the provision of access to federal information. The development of a comprehensive government-wide policy framework is needed to realize the promise offered by technology to improve public access to government information.

INTRODUCTION

Information producers and users alike have embraced electronic information technologies for the production and dissemination of electronic information resources. Information producers seek savings in the costs of producing and disseminating information, and both producers and users benefit from more timely dissemination of information and the greater ability to manipulate data disseminated in electronic formats. Because personal computers have become more affordable to a larger segment of the population and access to the Internet has become more widespread, electronic information resources have become increasingly accessible to individuals, businesses, and government agencies.

The federal government is one of the largest producers of information in the world. It has collected and disseminated information in a variety of electronic media and formats. Tangible information products have included magnetic tapes, to 5¼- and 3½-inch floppy disks, CD-ROMs, and DVDs. In addition to tangible products, throughout the 1990s there has been increasing on-line access to information housed in a wide variety of government databases and files accessible via dial-up bulletin boards and via the Internet. The electronic transformation of the Federal Depository Library Program (FDLP) began in 1989 with the distribution of the first CD-ROM to depository libraries, Census Test Disk Number 2, one of a number of pilot projects on disseminating electronic information to depository libraries, which were the result of much lobbying by the depository community. Through

the 1990s, the CD-ROM was the primary means of electronic information dissemination by FDLP. The number of titles distributed on CD-ROM peaked in 1998 and thereafter began a steady decline as online access replaced a growing number of titles formerly distributed on CD-ROM, print, and microfiche. By fiscal year 2001, about 60% of the titles in the FDLP were available online.^[1]

Also in 2001, the 107th Congress was considering two electronic government (e-gov) bills, and the president had embraced the concept of a "citizen-centered electronic government."^[2] Information technologies today play a major and ever-increasing role in the conduct of government business, and the access of citizens to information by and about their government will continue to be influenced by this transformation to an electronic federal information environment. Many of the policy issues being discussed today were first raised in the 1980s and early 1990s. These issues include questions of centralized versus decentralized dissemination and access points for federal electronic information and the role of the Government Printing Office (GPO) and the FDLP; concerns about the electronic information technologies creating the "information rich" and the "information poor"; concerns about the lack of a comprehensive policy framework addressing the life cycle of federal electronic information and the necessity of not only archiving or preserving it but also of ensuring persistent public access; and concerns about privacy, security, and ensuring the authenticity of federal electronic information resources. Other issues, such as debates over defining information as a public good or as a

commodity, and the privatization of government information, are also long-standing concerns that have resurfaced in part because of other pressures such as reducing the cost of government and the information industry's concerns over the proper roles of government and private business in the dissemination of government information.

MAJOR FEDERAL INFORMATION LAWS AND REGULATIONS

An informed citizenry has long been considered to be one of the cornerstones of our system of government, and our nation has a long tradition of providing public access to government information. In 1813, to inform the people of the actions of their government, an act was passed to authorize the distribution of the House and Senate Journals to selected libraries and historical institutions.^[3] By the late 1880s, the Government Printing Office was responsible for the depository library program. The depository system was expanded in the 1850s by the addition of congressionally designated libraries and was considered to be a "safety net" for making federal government information available to the public without cost to the individual user. The regional depositories, which were mandated to receive and retain a copy of all government publications, ensured long-term public access to the nation's historical record.

Throughout the past several decades, there has been a pronounced lack of a coherent overall policy framework for handling the dissemination of federal electronic information resources. Developments in information technology have made necessary a reexamination of the federal information laws and regulations that were created with printed information resources in mind, to incorporate access to electronic government information. New laws that addressed various aspects of the new information environment have been proposed during this time, and some have been enacted. An overview of the major laws and regulations related to government information dissemination can aid in understanding the current policy environment as well as public expectations for access to federal electronic information resources.

Title 44 United States Code: Public Printing and Documents

Title 44 of the U.S. Code is the statutory authority that gives the GPO's Superintendent of Documents responsibility for acquiring, classifying, cataloging, distributing to libraries, and ensuring the preservation of government publications. This centralized distribution system has been described as a funnel:

Before the advent of the Internet, a primary method of access to federal information was one in which the U.S.

Government Printing Office (GPO) acted as a funnel through which agency produced information resources were distributed to federal depository libraries. Depository libraries, physically dispersed throughout the United States, offered local access to federal information. This model has typified most existing federal information dissemination programs, including the Patent and Trademark Office's depository library program, the GPO sales program, and the Education Resources Information Clearinghouse and National Technical Information Service.^[4]

When agencies began to disseminate information in tangible electronic formats and online, the language of Title 44 was no longer adequate to accomplish its intent, providing for a centralized system to ensure the dissemination of and free public access to government information. The lack of statutory authority specifically requiring the dissemination of electronic information resources through the GPO to depository libraries has meant uneven compliance with the spirit of the law. Although some agencies have continued to use the GPO to distribute both their print and electronic information products, others have followed the guidance of the Office of Management and Budget (OMB), which, up until 1996, did not consider electronic products to be subject to Title 44. The various legislative efforts to revise the definition of government publications to include electronic information have all failed, including an attempt in the 105th Congress with Senate Bill 2288, the Wendell H. Ford Government Publications Reform Act of 1998, which sought a comprehensive reform of public printing and dissemination of government information in Title 44. The bill enjoyed the support of the library community and of the GPO, which saw it as "an important step forward in updating and modernizing the ability of the public to gain access to government information."^[5] It failed primarily because of opposition from private publishing and information technology groups.^[6]

The Paperwork Reduction Act (44 USC § 3501 et seq.)

The Paperwork Reduction Act (PRA), as first enacted in 1980 and amended in 1986, was an attempt to reduce the burden on the public of federal information collection and reporting requirements. This early PRA focused on cost-savings and efficiency, and one of its main effects was to discourage agencies from disseminating their information. In the PRA of 1995 (P.L. 104-13), public access to government information was specifically established as a responsibility of federal agencies. The PRA of 1995 instructs agencies to contribute to the Government Information Locator Service (GILS), an online inventory of federal government information that describes the content and location of their publications and records. It also established an Office of Information and Regulatory

Affairs (OIRA) within the Office of Management and Budget (OMB) to oversee agency information resources management activities and to develop information resources management policies, principles, standards, and guidelines. OMB's role in information resources management was revised and clarified by the PRA of 1995, in which the OMB was assigned oversight responsibility for information technology and for the life cycle of information resources in all formats. Under the PRA, each executive branch agency is responsible for its information resources management activities. The Information Technology Management Reform Act of 1996 (P.L. 104-106, Division E) amended the PRA by establishing a Central Information Officer (CIO) in each agency with the responsibility for its information technology programs and information resources management functions.

The primary directive issued by OMB in relation to its oversight of government information resources management policy is Circular A-130, *Management of Federal Information Resources*.^[7] As first issued in 1985, Circular A-130 treated government information as a commodity and encouraged executive branch agencies to look to the private sector for the dissemination of their information resources and to price their products based on cost-recovery. It also discouraged the distribution of agency information through the GPO and the FDLP. Revisions to the Circular in the 1990s reversed the OMB's earlier policy of limiting the government's role in disseminating its information. Circular A-130 now affirms that the free flow of information between the government and public is essential to a democratic society and that agencies are responsible for providing information to the public. It limits user fees to a level sufficient only to recover the cost of dissemination and also specifies that agency publications, including those disseminated electronically, must be provided to the GPO for distribution to depository libraries, a provision sought by the depository community for many years.

Government Printing Office Electronic Information Access Enhancement Act of 1993 (P.L. 103-40)

Although the definition of government publications in Title 44 has not yet been amended to include electronic information resources, the GPO was given a formal role in providing access to federal electronic information with the passage of the Government Printing Office Electronic Information Access Enhancement Act of 1993. Popularly known as the GPO Access Act, it directs the Superintendent of Documents to:

1. Maintain an electronic directory of federal electronic information.
2. Provide a system of online access to the *Congressional Record*, the *Federal Register*, and other appropriate

publications distributed by the Superintendent of Documents.

3. Operate an electronic storage facility for the federal electronic information made available on that system.
4. Accommodate as feasible, agency and departmental requests to have their information included in the system.

GPO Access debuted in June 1994. Although free access was given to depository libraries, an access fee to recover the cost of dissemination was charged to other users as provided for by the act. Free access was extended to the general public in December 1995.^[8]

Electronic Freedom of Information Act Amendments of 1996 (PL 104-231)

The Freedom of Information Act (FOIA) of 1966 (5 USC § 552) delineated the public's right of access to unpublished and unclassified federal agency records while protecting personal privacy and government security. As was the case with the definition of government publication in Title 44, agencies were not consistently interpreting the FOIA to include access to records in electronic form. The 1996 Electronic Freedom of Information Act (EFOIA) amended the FOIA and expanded the definition of a record to include electronic formats. It also mandated the establishment of "electronic reading rooms" to facilitate public access to major government records.

High Performance Computing Act of 1991 (P.L. 102-194)

The development of a national supernet of networks or "information superhighways" forming the backbone of a National Information Infrastructure (NII) was supported by the High Performance Computing Act of 1991. The act provided for a number of interrelated programs including high-performance computing research and development, the establishment of the National Research and Education Network (NREN) linking research institutions, government, and industry, and research and development of software and hardware. Federal agencies were to work with private network service providers, libraries, educational institutions, and others, to ensure that researchers, educators, and students had access to the network. The network would in turn provide access to a variety of electronic information resources including information from federal agencies and departments.

In 1993, the Clinton administration launched its National Information Infrastructure (NII) initiative to create partnerships between business, government, academia, and the public with the purpose of developing and extending access to the NII. Among the goals of the initiative were universal access, and improving the accessibility

of government information.^[9] The High Performance Computing Act was amended in 1998 by the Next Generation Initiative Research Act (P.L. 105-305), which continues the development of the NII by providing for the improving Internet capabilities, reliability, security, stability, and performance, and the development of advanced Internet applications. The act specifically recognized that an increasingly important role of the Internet is keeping citizens informed of the actions of their government.

IDENTIFYING AND LOCATING FEDERAL ELECTRONIC INFORMATION

Agencies are producing an increasing volume of their information products and services on a decentralized, local basis through the Internet. Nevertheless, public access to these web-based information resources may be limited, since they are not consistently included in the various existing government programs that foster information dissemination or information access, such as the FDLP, GPO Access, or NTIS.^[10]

GPO Access

In today's Internet environment, there is a strong trend to decentralized dissemination of federal electronic information, yet the GPO still plays a valuable role in providing access to federal electronic information. Through its GPO Access system it provides free access to a wide variety of federal government electronic information resources such as databases housed on the GPO Access servers containing regulatory, congressional, and agency information. GPO Access also hosts federal agency files available for download via GPO's Federal Bulletin Board, hosts some federal agency Web sites, and provides a variety of tools to locate government information. GPO's *Catalog of U.S. Government Publications*, one of the major indexes to federal government publications, contains not only records for tangible products distributed through the FDLP but also records for and links to resources in the FDLP Electronic Collection, a virtual library comprised of core regulatory and legislative information on GPO servers and selected remotely accessible products.^[11,12] A few of the other GPO Access finding aids include topical pathfinders to U.S. government information developed by volunteer government information librarians, an index to federal agency Internet sites, developed by government information librarians at Louisiana State University, and links to indexes created by federal agencies to identify their publications.

The National Technical Information Service

The National Technical Information Service (NTIS) has been another major clearinghouse of government information, specializing in government-funded scientific,

technical, engineering, and business related information. Under direction by the American Technology Pre-Eminence Act (ATPA) of 1991 (P.L. 102-245) to develop a comprehensive inventory of federal government information products and services, by 1992 it introduced FedWorld, a gateway to information available through federal agency bulletin boards.^[13] Today, FedWorld bills itself as "the online locator service for a comprehensive inventory of information disseminated by the Federal Government." Still offering its electronic gateway of more than 100 government bulletin boards, it also offers searching of agency Web sites and databases hosted by FedWorld and links to other government Web sites; a FedWorld FTP site contains more than 10,000 federal government data files. Although access to FedWorld is free, a number of the databases it offers are not.

The Government Information Locator Service (GILS)

Under the PRA of 1995, each agency is to establish and maintain an electronic agency information locator service to identify its major public information systems, holdings, and dissemination products, including electronic information resources. GILS records describe the information available in a resource and tell how to obtain or access the resource. Records describing resources accessible via the Internet should include a link to the resource.^[14] Taken as a whole, this distributed system of agency information locators forms the federal GILS.^[15] Uneven agency compliance with this decentralized approach to creating a governmentwide system has been one of its weaknesses. Other limitations are the lack of a single point of access that would truly define a federal GILS and that all agency GILS databases cannot be searched simultaneously. GPO Access offers the only cross-agency searching of GILS records, although it is limited to the 32 agency GILS databases it houses. It has also created pointer records describing and linking to the GILS of other agencies.^[16] FedWorld's GILS page offers a search form and list of agency GILS databases, but only one can be selected and searched at a time.^[17] Users have also been disappointed with the results of GILS searches because they expect to retrieve the full text of the resource instead of a description of it and information on how to get it.^[18]

Subject Portals

Most federal government entities are using the Web to provide public access to varying amounts of information by and about them. In 1995, at the direction of the House of Representatives, the Library of Congress developed a Web site called THOMAS to make federal legislative information freely available to the public over the Internet.^[19] THOMAS provides a search bill summary, status and text, voting, the Congressional Record, and committee

information. It also provides links to congressional reports and Web sites, directories, guides to the legislative process, and historical documents. Much of THOMAS' content, the text of congressional bills, reports, the *Congressional Record*, is obtained from the GPO, and THOMAS offers users the option of linking to the pdf. or text versions of these legislative resources on GPO Access.

The Department of Energy's Office of Scientific and Technical Information (OSTI) is a shining example of agency use of the Internet to make its information resources available to the public. In partnership with GPO, OSTI introduced its *DOE Information Bridge* in 1995, giving access to the full text of research and development reports from DOE national laboratories and grantees.^[20] OSTI has followed this well-received database with a number of others including the GreyLIT Network, a collaboration with the Department of Defense, NASA, and the Environmental Protection Agency.^[21] GreyLIT provides access to the full text of technical reports generated through federally funded research and development projects, resources that were previously difficult to identify and locate. OSTI is now involved in a partnership with a coalition of science agencies to create Science.gov, a unified gateway to their scientific and technical information resources in the physical and life sciences. Science.gov is projected to become public in early 2002.^[22,23]

FedStats, the "gateway to statistics from over 100 U.S. Federal agencies" is another cross-agency information-access partnership, providing a single location from which to discover federal government statistical information maintained on agency Web servers.^[24] Access points include alphabetical lists of topics and agencies and an option to search across all or selected agency Web sites. Other departments and agencies, such as the U.S. Department of Agriculture (USDA), partner with educational institutions for assistance with disseminating their electronic information resources. The Mann Library at Cornell University hosts the Department of Agriculture Economics and Statistics System containing reports and data sets from USDA economics agencies.^[25]

Web Search Engines

FirstGov is the latest "comprehensive" locator to emerge from the federal government.^[26] An executive branch initiative administered by the General Services Administration, FirstGov was launched in September 2000 amidst a storm of publicity. Introduced by President Clinton, FirstGov was embraced by the Bush administration as an essential building block of a citizen-centered e-government.^[27] It is touted as the "only official U.S. Government portal to 47 million pages of government information, services, and online transactions" and offers both a search engine and topical and agency directories.^[28] On its release, it was found lacking in its general and apparently haphazard topical directory structure and in the poor performance and simple search

features offered by its search engine.^[29] Its search engine has since improved, and the directory structure is currently under revision. Publicity for FirstGov overlooks the existence of GPO Access and other governmentally sponsored locators such as THOMAS, and how these other information providers and locators are to be integrated with FirstGov is not clear. Currently, FirstGov includes links to the GPO Access and DOE databases and to THOMAS under its "Reference Shelf." Although initially FirstGov did poorly in comparison to other major search engines at retrieving GPO Access pages, GPO Access has had some success in working with FirstGov to improve its search engine's retrieval from databases on the GPO Access servers. One study found FirstGov gave the best performance of 23 major search engines in retrieving information from GPO Access.^[30]

Several other search engines focus on government Web sites, including usgovsearch and Google Uncle Sam.^[31,32] Usgovsearch is a joint venture between NTIS and Northern Light and searches the citations and abstracts of material in the NTIS database, selected government Web sites, and Northern Light's Special Collection, a library of full-text journals, books, magazines, newswires, and reference sources. Searching usgovsearch is free, but there is a charge to retrieve the text of material from the NTIS Archive and the Special Collection. Google Uncle Sam is an option offered by the popular Google search engine that restricts searches to .gov and .mil domains. Although using Google Uncle Sam does limit retrieval to government Web sites, it also includes other levels of government using the .gov domain such as state government Web sites, and it omits Web sites in .org, .edu., .net, and .com domains with government information such as those created with partners in educational institutions. However, a great advantage either version of Google has over other search engines, including FirstGov, derives from the fact that a large amount of government information is posted to the Web as pdf files and other non-HTML formats, and Google is the only search engine to search non-HTML file types such as pdf and Microsoft Office documents.

Despite FirstGov's claims that its search engine searches every word of every U.S. government document, no single search engine retrieves all of the government information available on or through the Internet. Because of different searching and ranking methods, different search engines find and offer overlapping but different retrieval sets. Nonetheless, some or all material lurking in the "invisible Web" and the "opaque Web" eludes every search engine. This includes material that is accessible to the search engine but is not indexed for reasons including restrictions on the depth of crawl (amount of material indexed on a single site), frequency with which sites are revisited and reindexed, or that the crawler is not aware of the web page. It also includes pages not accessible to search engines such as databases that require registration to search and resources that require interaction such as the

selection of variables that generates a custom page.^[33] The Census Bureau's American FactFinder, THOMAS, and the GPO Access databases are examples of deep Web resource.^[34] The best strategy to use in searching for federal government information accessible via the Web is to use multiple search engines in combination with subject directories, the various cross-agency tools such as offered by GPO Access, and NTIS, and to mine government agency sites by browsing and using their own site search engines and databases.

OTHER INFORMATION POLICY ISSUES

Variation and Obsolescence of Media and Formats

The variety of formats and media used to distribute government information was shown in the *Assessment of Electronic Government Information Products*.^[35] This wide variety, together with the frequent lack of accompanying documentation, creates difficulties in providing access. Access to information distributed in older formats and media, such as the 5¼-inch floppy disks, is also threatened and sometimes lost because the required equipment or software is no longer available. Historical research and time series comparisons can be hindered because over time agencies have distributed data in a variety of formats and media. Several projects initiated by depository librarians are attempting to ameliorate some of these barriers to access. The GODORT CD-ROM Documentation Service provides bibliographic, content, use, technical, and management information for government-produced and government-related CD-ROMs, DVDs, and floppy disks.^[36] The Floppy Disk Project at the Indiana University Bloomington campus provides a central location through which floppy disks that were distributed through the FDLP, and of which many are no longer accessible locally, can be located and downloaded.^[37] Two projects illustrative of attempts to deal with the variation in user interfaces are the Oregon State University's Government Information Sharing Project, which provides Web access to a variety of federal statistical information issued through the FDLP on CD-ROM, and the University of California's announced Counting California, which has developed a single interface to data compiled by a growing number of federal, state, and local agencies.^[38,39]

Economics of Access to Information

The initial use of electronic publishing technologies by agencies was to produce a less expensive printed product. It is now common for information to remain in electronic form from creation through dissemination. Although this may yield cost savings for the publisher, it can be viewed as a cost increase for the end user who now bears the cost

of the equipment and software required to gain access to the electronic product, as well as the cost of printing the material as needed. Because it is becoming increasingly necessary for citizens to have access to computers and the Internet to connect with government information and services, there have been a variety of studies and reports on measures of "digital inclusion." Census Bureau surveys have shown a dramatic increase in the percentage of households with computers, from 8.2% to 51% between 1984 and 2000, and households with access to the Internet have increased from 18.0% in 1997 to 41.5% in 2000.^[40] Although there were increases in computer ownership and Internet access across socioeconomic and geographic groups, "noticeable divides still exist between those with different levels of income and education, different racial and ethnic groups, old and young, single and dual-parent families, and those with and without disabilities."^[41] However, an even greater divide is apparent when looking at high-speed, high-capacity, or broadband connections, because only half of those with access to the Internet have the option of a broadband connection. The 12% of Internet users who do subscribe to a broadband service tend to be of a higher income level and live in large metropolitan areas.^[42]

The burden of the cost shift to the information user is exacerbated by the trend to commercialize or privatize government information. Commercialization refers to agencies that, by choice or by mandate, treat government information resources as a commodity and recover costs or generate revenues from their sale. An example of this is the National Technical Information Service, which is mandated by the American Technology Pre-Eminence Act of 1991 to be self-supporting. It sells access to its own database as well as to many of the agency databases it distributes, for example, the Department of Labor's Davis-Bacon Wage Determination Database. The Davis-Bacon database has been made available without charge through GPO, unlike some other commercialized resources such as the federal courts' PACER (Public Access to Court Electronic Records) system. PACER is funded through the collection of user fees by direction of congress and provides access to electronic versions of the opinions of the lower federal courts. Although some of the courts provide users free access to the actual opinions, others only link to the fee-based PACER. No free alternatives are available to the user because PACER is not made available without charge to depository libraries. The dissemination practices even within a commercialized program are not necessarily consistent, as seen with STAT-USA, an agency in the Economics and Statistics Administration of the U.S. Department of Commerce. It is also required by law to be self-sustaining but manages to acknowledge Title 44 by providing depository libraries with one-password access to its main databases, State of the Nation, and GLOBUS and NTDB. It does not, however, extend this to its USA Trade[®] Online database, a

STAT-USA and U.S. Census Bureau, Foreign Trade Division collaboration.^[43-46]

Privatization refers to federal agencies making exclusive contracts with the private sector, which “adds value” to and disseminates government information resources. A well-publicized example of privatization and the problems it can create for public access is the U.S. Department of Justice’s contract with the West Publishing Company to maintain its database of case law and digests:

JURIS includes a mix of non-copyrighable, public domain government information with proprietary information created by West Publishing Company. The JURIS database exemplifies the loss of government information to the public when an agency enters into an exclusive contract with a private entity without including in the licensing agreement provisions for public access mandated under Title 44. To this day, parts of the JURIS database, including its public domain content, is still controlled by West Publishing Company and public access, even under the Freedom of Information Act (FOIA), is prohibited.^[47]

In contrast, although its dissemination subsystem is privatized, the U.S. Security and Exchange Commission’s EDGAR (Electronic Data Gathering, Analysis, and Retrieval) database provides free public access through the SEC Web site.^[48] The private sector has been vocal in its campaign to claim a larger and more exclusive role in the dissemination of government information resources and sees any value-adding activity as an encroachment onto the private sector’s turf.^[49] In the electronic information environment, an agency that creates software to provide public access to its own databases is seen by the information industry to be adding value and, therefore, engaging in inappropriate competition. The information industry also objects to projects such as PubScience, the Department of Energy’s (DOE) database of citations with abstracts to peer-reviewed journal literature in the physical sciences and other disciplines of concern to the DOE.^[50] DOE created the database and makes it available to the public for free as part of its mission to provide for the accessibility and dissemination of scientific information. The challenge to PubScience raises concerns that similar agency indexing projects, such as the National Library of Medicine’s PubMed and the Education Department’s ERIC database, may be forthcoming.^[51-53]

The Safety Net

Disparities in access to information technology and the varying abilities to of citizens to pay the access fee for commercialized or privatized information has raised concerns that the government is participating in the creation of an information-rich and an information-poor situation. The government has recognized the necessity of connecting

libraries to the Internet to help provide access to those without access at home.^[54] However, access to the information technology is only part of the equation. Librarians have long maintained that to ensure equitable access in the spirit of Title 44, depository libraries should have free access to databases and other electronic information products created by the government whether they are distributed by the government.

Privacy, Security, and Authenticity

The push to widespread implementation of e-government initiatives has heightened concerns for data privacy, security, and authenticity, and aspects of these issues are directly relevant to a discussion of federal electronic information resources. The Privacy Act of 1976 (P.L. 93-579) addressed aspects of personal privacy protection and restricted the ability of the federal government to collect and disclose personal information. It was amended in 1988 by the Computer Matching and Privacy Protection Act (P. L. 100-503), which regulates federal agency use of personally identifiable records in computer matching programs. The 1998 amendment applies only to records in systems subject to the Privacy Act and excludes matches performed for certain purposes such as statistics, law enforcement, and research. Maintaining the confidentiality of data is an ongoing concern for, as technologies continue to make it easier to access and share data, agencies and researchers see efficiencies and advantages in sharing and “repurposing” or linking data collected from multiple sources:

Record linkage projects like these raise privacy issues, such as whether consent to linkage was obtained; whether linkages required sharing identifiable data with other organizations; and whether “deidentified” linked data are subject to reidentification risks when released for research or other uses.^[55]

If people are not convinced about the confidentiality of their responses to government surveys and other data collection efforts, the reliability of those surveys and databases will decrease. Access to government data might be severely curtailed as an answer to privacy concerns, a reaction researchers and the data community hope to avoid.^[56]

Another privacy concern is the collection of personal information about individuals who use government Web sites. OMB’s Memorandum M-99-18 directed agencies to post on privacy policies on their principal Web sites to disclose what information is collected, why, and how it will be used. It was followed by M-00-13, which specified that the presumption should be that “cookies,” which can be used to track an individual’s use of Web sites, will not be used by federal Web sites.^[57,58]

The Computer Security Act of 1987 (P.L. 100-235) established minimum security standards for federal computer

systems. The Government Information Security Reform, Act (P.L.106-398 Title X, subtitle G) was an amendment to the PRA of 1995 requiring each agency to develop, implement, and maintain a security program and plan. Each agency must ensure the integrity, confidentiality, authenticity, availability, and nonrepudiation of information and information systems. Authenticity and nonrepudiation were addressed by the Government Paperwork Elimination Act (GPRA) of 1998 (P.L.105-277 Title XVII), which also amended the PRA to facilitate e-government by requiring agencies to make electronic versions of their forms available and allow the use of electronic signatures to file the forms electronically. One of the applications of electronic signature technologies is to ensure the recipient of downloaded federal electronic information that they have received a complete and unaltered copy of that information. The GPO is pursuing the use of public key infrastructure (PKI) technology to validate that the user has received the official text of congressional bills that reside on GPO Access.^[59]

Permanent Public Access

Elimination of tangible government resources without a clear and systematic policy for electronic preservation and retention could greatly increase the number of fugitive federal documents and result in the deletion of important unique materials from computer systems.^[60]

Historically, libraries in the Federal Depository Library Program were responsible for providing permanent access at no cost to the public for the government information products in tangible formats that were distributed through the program. Their role in providing permanent access focuses on public access to reference copies of publications and is distinct from that of the National Archives and Records Administration, which preserves an official copy of federal government records, including electronic records in its Center for Electronic Records. Permanent access in the electronic environment involves technological aspects of preservation, such as refreshing or transferring data from one medium to another and reformatting information due to software or platform obsolescence.^[61] It also involves making the information accessible to the public on a continuing and indefinite basis in some online mode and/or through the collections of depository libraries. With the decentralized dissemination of online publications and databases combined with the lack of a centralized information policy, it is alarming but not surprising that much federal electronic information is neither making it into the depository system as tangible products for dissemination and permanent public access, nor are agencies themselves ensuring permanent access to their own information resources. Electronic-only publications

are easily revised or removed altogether, including annual reports and statistical publications from previous years.^[62] Dynamic databases, allowing the creation of a "publication" tailored to an individual user that ceases to exist at the end of the session, are an advantage of the on-line environment, yet they are also endangered information if provisions are not made for the permanent accessibility of either the database or at the least, of prepackaged publications derived from the database.

The GPO has taken a number of steps to address the issues regarding preservation of and access to federal electronic information. The FDLP Electronic Collection Archive, established by authority of the GPO Access Act, contains "publications which are identified, described, and pointed to as part of the FDLP Electronic Collection and which are not part of the FDLP in any other form nor guaranteed to be permanently available by their issuing agency or entity."^[63] GPO also coordinates a Permanent Public Access Working Group with participants from federal agencies, national libraries, congressional committees, the GPO and the FDLP, and public interest organizations.^[64] Partnership agreements between GPO and federal agencies, such as DOE and the National Library of Medicine, ensure that content from their Web sites will be permanently available. The GPO also enters into content partnerships with depository libraries, who agree to host part of the electronic Permanent Online Collection for free use by the public. Two examples of content partnerships are Department of State Foreign Affairs Network (DOSFAN), a partnership with the U.S. Department of State and the University of Illinois at Chicago, and the "cybercemetery" at University of North Texas Libraries, which provides permanent online access to electronic publications of selected federal government agencies that have ceased operation.^[65] Although these initiatives by the GPO to ensure permanent public access are still evolving, there is still much federal electronic information that is being missed by these efforts. Concerns have also been voiced about the loss of the safe redundancy offered by the depository system with multiple copies housed in collections across the nation and the shift of responsibility for permanent public access from libraries to the government. In response, it has been suggested that GPO acquire agency databases and digital versions of government publications posted on agency Web sites and make them available for selection by digital depository libraries.^[66]

CONCLUSION

The dissemination of federal information in electronic form, and in particular the use of the Internet, offer the opportunity to provide more timely, convenient, and widespread access to government information resources. However, identifying and locating needed government

information can be difficult and frustrating for users attempting to navigate the fragmented and complex federal information landscape. This fragmentation is seen in the overwhelming number of federal Web sites that lack central coordination, even within a specific organizational hierarchy (e.g., departmental or legislative). It also appears in the varying media and formats in which the information may be offered and in the use of partnerships and privatization to distribute government information. Navigation is made more difficult by the fact that government information offered via the Web frequently changes location or apparently entirely disappears. The existence of multiple comprehensive locators, GPO Access, FedWorld, and the GILS, all established at the direction of Congress, and the Executive Branch's FirstGov, illustrates the lack of an overall strategy for the provision of access to federal information. Although overlap and multiple points of access are not inherently bad, the lack of a unified vision and coordination of effort, as well as competition for funding, weaken the overall effort to provide access to federal information.

The development of a comprehensive governmentwide policy framework is needed to realize the promise offered by technology to improve public access to government information. Such a framework should incorporate the strong foundation of the past as embodied in the Federal Depository Library Program. Five principles for the dissemination of and access to federal government information were offered in the *Study to Identify Measures Necessary for a Successful Transition to a More Electronic Depository Library Program*:

1. The Public has the right of access to government information.
2. The government has an obligation to disseminate and provide broad public access to its information.
3. The government has an obligation to guarantee the authenticity and integrity of its information.
4. The government has an obligation to preserve its information.
5. Government information created or compiled by government employees or at government expense should remain in the public domain.^[67]

Long overdue and made more urgent because much government information is increasingly available only electronically, perhaps the current move to e-government with its discussions of electronic access to government information and services will help bring about a review and reform of national information policy. A new comprehensive federal information policy framework that incorporates these historical principles and encompasses federal electronic information resources would recognize the vital role government information plays in the nation's economy, scientific, technical, and educational endeavors, and in our system of governance.

Film and Broadcast Archives

Karen F. Gracy

School of Library and Information Science, Kent State University, Kent, Ohio, U.S.A.

Karen E. King

Washington, District of Columbia, U.S.A.

Abstract

Film and broadcast archives serve as repositories for moving image and sound resources. Whether found in commercial or noncommercial settings, these archives aim to collect, describe, preserve, and make accessible audiovisual materials for users. Archives face many challenges in maintaining film, video, and audio materials, including physical deterioration, format obsolescence, and storage requirements. Audiovisual collections also require significant investment in appraisal, metadata generation for description, and access technologies. The abandonment of the motion picture film as a format for distribution and exhibition and the narrowing window of opportunity to transfer analog magnetic media will continue to drive the archival agenda. Copyright legislation, such as the Copyright Term Extension Act and the Digital Millennium Copyright Act, also complicate the mission of audiovisual archives to preserve and provide access to their materials.

INTRODUCTION

This entry aims to familiarize readers with the mission, goals, and activities of film and broadcast archives, which serve as the repositories for moving image and sound resources. These organizations, which may be found in commercial and noncommercial settings, aim to collect, describe, preserve, and make accessible audiovisual materials for users. While commercial archives tend to focus on the maintenance of collections for the purposes of republication in ancillary markets such as CDs and DVDs, web streaming, or for reuse in new productions, noncommercial archives more often aim to serve users interested in using moving images and audio for educational, artistic, or research purposes. Film and broadcast collections can be found in a variety of settings, including libraries, museums, archives, universities, radio and television news stations, corporations, and many other organizations where these materials are produced and used for education, information, or entertainment purposes.

Film and broadcast archives face unique challenges in providing the same sort of services that are often taken for granted by libraries and traditional archives. Audiovisual material requires different approaches and tools for its appraisal, description, access, and preservation. Yet, the current demand for visual and aural resources to enrich education, scholarship, news services, and entertainment means that institutions and organizations must invest in these rich sources of information.

This entry discusses the major institutions and organizations involved in audiovisual archiving, the scope of activities in which they are involved (including preservation,

appraisal, cataloging and description, and access), and key issues archives are currently facing, including the transition from analog to digital formats, intellectual property concerns, funding for preservation of film and broadcast material, and educational opportunities for audiovisual archivists.

DEFINITION AND CHARACTERIZATION OF MOVING IMAGE ARCHIVES

Film Archives

Although collections of motion pictures were accumulated early on after the introduction and commercial exploitation of film in the 1890s, primarily by the distributors and exhibitors of early films, the prevailing attitude at the time of those involved in the motion picture industry was that films were disposable commodities rather than being seen as the subjects of study or artistic appreciation. This attitude changed quickly as intellectuals and film fans began to articulate the importance of motion pictures as cultural artifacts and information sources and clamored for the long-term retention of films for posterity.

The desire to provide a more permanent haven for film accelerated as the silent era drew to a close, when many motion picture studios attempted to jettison their libraries in the wake of sound film. The fear that the first decades of film would be lost encouraged several individuals to found organizations dedicated to the protection and exhibition of what were considered to be treasures of film heritage.^[1]

By the early 1930s, the first film archives recognized as such emerged in the United States and Europe. Operating primarily as either national repositories or collections within larger cultural institutions, these archives soon formed an international association known as the International Federation of Film Archives (FIAF) in 1938.^[2] Founding members of FIAF included the Cinémathèque Française, the Museum of Modern Art Film Library in New York, the British Film Institute (BFI) National Film Library, and Germany's Reichsfilmarchiv. The establishment of cultural institutions devoted to the care of film heritage was evidence that films were beginning to be taken seriously as cultural artifacts and information sources. Readers interested in further information about the history of the film archive movement should consult Steven Ricci's article on this subject, found in this volume.

Collections of motion picture film were first amassed in the early decades of the twentieth century, as producers of films—production companies—began to build up their film libraries. Early film archives had mixed success in getting studios to donate material from their libraries to archive collections, due to fears that archives would somehow exploit films in violation of copyright law.^[1] Some of this initial antagonism was overcome by the 1970s, however, as studios began to look for ways to unburden themselves from the expenses of storing large quantities of nitrate film and later, 16 mm television prints.^[3] In this manner, a number of archives in the United States acquired access copies of the first half-century of motion picture production. Due to copyright deposit requirements, the Library of Congress has amassed the largest collection of film in the United States, and one of the largest in the world. Table 1 summarizes the most prominent film collections in the United States, including size of collections and strengths. For an extensive list of film archives and research centers throughout the world, please consult the website of the Library of Congress, which maintains a directory.^[4] Many commercial copyright owners maintain their own library of titles and footage, and thus must also be considered as important sources for film resources. These libraries are maintained primarily for the purposes of commercial exploitation, rather than as public resources, however.

Outside of the United States, many archives have acquired copies of films through deposit laws that require production companies to give copies of films, particularly those financed in whole or in part by the government, to the national archive. For a complete list of European Union countries that have deposit laws, please consult the list compiled by the International Federation of Film Producers Associations (FIAPF).^[5]

Broadcast Archives and Collections

Until quite recently, producers of broadcast radio and television in the United States had an inconsistent record of

preserving their productions for long-term retention. While some earliest productions were captured on transcription discs (in the case of radio), or on film (for early television), the switch to videotape, which began in the 1950s with the introduction of the earliest formats and became near universal by the late 1960s/early 1970s, meant that content often was seen as more disposable. Due to the expense of the new magnetic medium, it was quite common for commercial stations to erase and reuse the newly adopted tape. While certain news and entertainment segments were seen as having potential for reuse in other programs, others were quickly deleted to make way for new programming. Yet, many commercial stations still own unique historic material that has great use in education, research, and other uses.^[6] The television and video archives movement in North America was a response to the new use of videotape for education and documentation. Furthermore, the 1976 revision of the American copyright law encouraged off-air taping of hard news broadcasts and established the new American Television and Radio Archives.^[7]

Broadcast archives and collections exist in many different sizes and formats throughout the world. Table 2 summarizes the most well-known broadcast archives collections in the United States, Europe, and Asia, including size of collections and strengths.

The following section will describe various archives and collections throughout the world, which may be categorized as academic, museum, government, or station collections.

Academic Collections

The United States has many different academic broadcast collections covering both television and radio, commercial and noncommercial. First, Special Collections in Mass Media & Culture (SCMMC), as a unit of Special Collections and University Archives at the University of Maryland Libraries, holds a wide-ranging assortment of resources documenting the history of commercial, public, and educational radio and television broadcasting, through its two component collections, the National Public Broadcasting Archives (NPBA) and the Library of American Broadcasting. SCMMC also has substantial secondary resources in the areas of cinema, print journalism, and humor studies.^[8]

The first organized library of radio history was the Broadcast Pioneers Library, which began in 1972. From 1964 to 1971, former National Broadcasting Company (NBC) executive William S. Hedges collected items for the Broadcast Pioneers History Project. These materials, comprising approximately 13,000 items, including correspondence, articles, and speeches, formed the core collection of the Broadcast Pioneers Library and were housed in the National Association of Broadcasters' (NAB) headquarters in Washington, DC, until 1994. That year, it

Table 1 Major motion picture archives in the United States (collections consisting of at least 10,000 titles, items, or equivalent).

Archive	Collection size	Collection strengths
Academy Film Archive ^a	Over 190,000 items	Academy Award–nominated films; film and television programs relating to the Academy Awards shows; documentary film holdings including the collection of the International Documentary Association; home movies and amateur films, particularly those related to the history of Hollywood, the motion picture industry, and the history of the Los Angeles region
Archive Films (parent company is Getty Images) ^b	31,000 titles	Documentaries; news footage; actualities; industrial films
George Eastman House ^c	More than 28,000 titles; collection of stills, posters, and papers with over 3 million artifacts	Silent film; personal film collections of directors Kathryn Bigelow, Ken Burns, Cecil B. DeMille, Norman Jewison, Spike Lee, and Martin Scorsese; largest collection of nitrate Technicolor negatives in the United States
Human Studies Film Archives, Smithsonian Institution ^d	Approximately eight million feet of film and video	Ethnographic film
Indiana University Libraries Moving Image Archive ^e	More than 86,000 items	Educational film and video collections, many produced by Indiana University
Library of Congress ^f	More than 400,000 titles (approximately 750,000 items)	Studio features; independent features, documentaries; newsreels; animation; trailers
Museum of Modern Art (NY) ^g	More than 22,000 films; four million film stills	International cinema; silent film (particularly Biograph and Edison companies, and the films of D.W. Griffith); circulating collection of more than 1200 16 mm prints that include many classics of world cinema
National Archives and Records Administration ^h	Nearly 300,000 motion picture films; more than 200,000 sound and video recordings	Universal Newsreel collection; motion pictures created by the U.S. Armed Forces; Ford Motor Company Collection; U.S. Atomic Energy Commission
Northeast Historic Film ⁱ	900 collections; 29,000 individual items	Film and videotape related to the northern New England region (Maine, New Hampshire, Vermont, and Massachusetts); major collections include film and videotape originating from television stations or created primarily for broadcast, industrial works created by and for corporate and industrial entities, professionally created fictional works, titles made by independent creators intended for public viewing, and amateur films
Pacific Film Archive ^j	More than 16,000 films and videos	International features (particularly Japan, Soviet Union, Eastern Europe, and Central Asia); studio features; independent features; documentaries; experimental/avant-garde films; educational films; animation; trailers
UCLA Film and Television Archive ^k	More than 350,000 films and 160,000 television programs; 27 million feet of newsreel footage	35 mm collections from Paramount Pictures, Twentieth Century Fox, Warner Bros., Columbia Pictures, New World Pictures, Orion Pictures, RKO Pictures, and Republic Pictures; Hearst Metrotone newsreels; 16 mm film collection of over 5000 titles; animation; live-action shorts; personal donations from William Wyler, Jean Renoir, King Vidor, George Pal, Stanley Kramer, Tony Curtis, and Robert Aldrich

moved to the University of Maryland and changed its name to the Library of American Broadcasting (LAB). The LAB collection, which is one of the most extensive collections in the history of broadcasting, includes audiovisual materials, books, photographs, pamphlets, periodicals, manuscripts, oral histories, and scripts pertaining to the history of the field.^[9]

The NPBA is another academic broadcast collection. Since it began in June 1990 at the University of Maryland, NPBA's mission has been to preserve and make accessible the archival record of the major organizations of public broadcasting, to archive personal papers of individuals who made significant contributions to educational and public broadcasting, and to provide archival services to several Washington, DC, metropolitan area public stations. While NPBA's first concern is textual material, it also has a growing audiovisual component.^[10]

Other academic collections of note include the Wisconsin Historical Society's Mass Communications History Collections, the UCLA Film & Television Archive, and the Vanderbilt Television News Archive. The Wisconsin Historical Society's Mass Communications Collection began in 1955 with the purpose of documenting the importance of mass media in twentieth century American life. Its collections include the records of NBC, the Association of Education in Journalism and Mass Communications, and National Educational Television (NET), as well as

the papers of David Brinkley, H.V. Kaltenborn, and Howard K. Smith.^[11]

The UCLA Film & Television Archive, the second largest moving image archive in the United States, began in 1965, when the Academy of Television Arts and Sciences and the UCLA Theater Arts Department created the ATAS/UCLA Television Library. In 1976, the Television Library merged with the Film Archive to become the UCLA Film & Television Archive.^[12]

Finally, the Vanderbilt Television News Archive began in August 1968 with the mission of preserving and providing access to television newscasts from U.S. national news networks. It operates in conjunction with the Motion Picture, Broadcasting and Recorded Sound Division of the Library of Congress, providing copies for the Library's permanent collection.^[13]

Museums and Libraries

Prominent museums and libraries with broadcasting collections include the Museum of Broadcast Communications (MBC), the Paley Center for Media, and the Thousand Oaks Library collection. The MBC, located in Chicago, Illinois, is a combination of archive, media arts center, educational institution, and museum. Since 1987, the MBC collects and preserves historic and contemporary broadcasting content in order to educate and entertain

Table 2 Major broadcast archives and collections worldwide (consisting of at least 10,000 titles, items, or equivalent).

Archive	Collection size	Collection strength
Special Collections in Mass Media and Culture—Library of American Broadcasting (LAB), National Public Broadcasting Archives (NPBA) ^a	10,000 books and monographs, 8,000 broadcasting industry pamphlets, 93,000 audiotapes of various formats, 20,000 audio CDs, 11,000 videotapes of various formats, 1,000 films and kinescopes, 8,000 recorded discs, 2,500 radio and television scripts, 300,000 photographs	Extensive collections making the past and present of commercial and noncommercial broadcasting widely accessible. Key NPBA collections include Archives of the Corporation for Public Broadcasting, National Public Radio, Children's Television Workshop, WAMU-FM Programming Archives, C. Scott Fletcher Papers, and James Day Papers. Key LAB collections include WNET-Thirteen Arthur Godfrey Collection, <i>Vox Pop</i> Program Collection, Radio Advertising Bureau (RAB) Collection
Wisconsin Historical Society. Mass Communications History Collections ^b	1000 ft ³ of paper collections, more than 5000 audio recordings, and more than 500 films	Papers of significant individuals, organizations, corporations in mass communications including NET, David Brinkley, and Joseph Hanna
UCLA Film and Television Archives ^c	More than 350,000 films and 160,000 television programs, more than 100,000 News and Public Affairs programs, more than 2,000 radio programs	Materials cover broadcast history such as DuMont TV, the Hearst Metrotone News, news and public affairs taped off-air from 1979 to 2003
Vanderbilt Television News Archive ^d	More than 60,000 news broadcasts from NBC, ABC, CBS, Fox, and CNN	Materials span the presidential administrations from Johnson to Obama. Notable topics covered include political conventions, presidential speeches, events of September 11, 2001, the Persian Gulf War, and the wars in Afghanistan and Iraq
Museum of Broadcast Communications (MBC) ^e	Scores of radio memorabilia, working radio and television studios, etc. 62,000 ft ² facility that includes the National Radio Hall of Fame	Films, videos, photographs, audio recordings, and scripts representing genres including television entertainment, television news, and instructional/educational programming
Paley Center for Media ^f	Nearly 140,000 programs and advertisements	Documents the intersection between media and society through collections and public events
Library of Congress ^g	Approximately 80,000 television programs	Examples include the NBC Collection comprising a wide variety of genre programming and the NET Collection with more than 10,000 titles from early noncommercial U.S. television
WGBH Media Archives and Preservation Center ^h	More than 1 million audiovisual materials accessed through Open Vault	Examples include television series like "Vietnam: A Television History," "American Playhouse," and "The French Chef"
Pacifica Radio Archives ⁱ	More than 50,000 recordings	Programs document political, cultural, and artistic movements since the 1950s
United Kingdom		
British Broadcasting Company (BBC) Sound Archive ^j	Over 1 million discs, 185,000 tapes, and many other sound and video recordings from all over the world	Includes off-air radio programs since 1960, and off-air television programs since 1980. Subjects include music, drama, literature, oral history, and wildlife sound
BBC Written Archives Centre ^k	Thousands of files, scripts, and working papers	Documents BBC history from formation in 1922 to the 1980s; other topics include history and development of mass communication and changes in popular culture
National Archive, British Film Institute ^l	Nearly one million film and television titles.	Rich resource of British television programming

(Continued)

Table 2 Major broadcast archives and collections worldwide (consisting of at least 10,000 titles, items, or equivalent). (Continued)

Archive	Collection size	Collection strength
National Media Museum ^m	More than 3.5 million items of television history including television receivers, studio equipment, and video recorders	Documents the technological evolution of television and film
Japan		
Nippon Hoso Kyokai (NHK) ⁿ	More than 8 million news and program items	Documents Japanese programs, both current and historical
Canada		
Canadian Broadcasting Company (CBC) Program Archives ^o	Millions of discs, tapes, films, photographs, written records, and computer files	Documents 70 years of Canadian radio and television history
Australia		
Australian Broadcasting Corporation (ABC) Archives and Library Services ^p	More than 100,000 radio and television programs, photographs, and documents	Documents Australian media created since 1932
National Film and Sound Archive ^q	More than 2.3 million films, radio programs, television programs, videos, audiotapes, etc.	Documents Australia's audiovisual heritage

visitors and researchers through various outreach activities including public programs, exhibits, on-site visits to the archives, and online access.^[14] Formerly known as The Museum of Television and Radio, the Paley Center has a large collection of television and radio programming documenting 100 years of media history.^[15]

The American Radio Archives, found in the Special Collections Department of the Thousand Oaks Library System, California, has an extensive broadcast document collection including thousands of radio and television scripts, pamphlets, sound recordings, manuscripts, and personal papers. The library also holds personal papers of people such as Norman Corwin and Rudy Vallee.^[16]

Government

The Library of Congress began collecting and preserving radio and television programs in the 1940s. In 1976, the Copyright Act established the American Television and Radio Archives at the Library of Congress, which is now administered by the Motion Picture, Broadcasting and Recorded Sound Division.^[17] This collection contains approximately 80,000 television programs, focusing on prime-time entertainment series. For example, the NBC Collection consists of a wide variety of genre programming including sports and children's programs from 1948 to 1977. Its NET Collection has over 10,000 titles from

early noncommercial U.S. television.^[18] In 1993, after years of negotiations, the Library of Congress agreed to accession all programs aired and retained by Public Broadcast Service (PBS), which could exceed over 100,000 items.^[17]

The National Archives and Records Administration (NARA) is the other governmental body with a significant amount of broadcast-related material. Examples include the Records of the Federal Communications Commission (FCC).^[19] and the Records of the National Telecommunications and Information Administration (NTIA).^[20]

Broadcasting Stations

Many stations either have their own archives or work with local universities and historical societies when appropriate. For example, while the NPBA cannot serve as a central repository for all public broadcasting stations, NPBA's mission includes advising stations to create archival agreements with local universities and historical societies.^[10] One prominent public broadcasting station archive is the WGBH Media Archives and Preservation Center. Established in 1978 as part of the Film Operations Department, its collection mostly consists of nearly 1 million audio, video, and digital assets. With funding support from the Andrew W. Mellon Foundation, the WGBH MLA created Open Vault, an online media archive content delivery system for academic and research use.^[21]

The Pacifica Radio Archives, described as "... one of the oldest and most important audio collections in the world," has audio material from five member stations ranging from documentaries to poetry readings. Its mission is to "... appraise, collect, organize, describe, and preserve the creative work generated by or produced in association with Pacifica Radio... and to make it available for reference and research use".^[22]

INTERNATIONAL

On the international scene, broadcast collections tend to be less widely dispersed, as stations are usually government owned. This section will look at broadcast archives and their respective repositories in the United Kingdom, Japan, Canada, and Australia.

United Kingdom

In the United Kingdom, the broadcasting collections range from materials aired by the public service television entity, the British Broadcasting Company (BBC), and the commercial broadcasters, Independent Television News (ITN) and Thames Television, as well as material located at the BFI.

The BBC began under a Royal Charter of Incorporation in 1927, granted when the company was a radio organization. The BBC is mostly funded through a license fee

system with supplemental income through foreign sales and cable and satellite contracts. It is a national broadcaster based in London with eight regional studios in England and other studios in Wales, Scotland, and Northern Ireland.^[23] Selected BBC radio and television programs are archived in the BBC Sound Archive at the British Library with its holdings reflecting trends and interests of different generations. The holdings include off-air radio programs since 1960 and off-air television programs since the late 1980s with subjects such as music, drama, literature, oral history, and wildlife sound.^[24] The BBC written documentation is archived in the BBC Written Archives Centre, located in Reading. The Centre has material that documents the history of past programming (more than 3 years old), the history and development of mass communication, and changes in tastes and popular culture.^[25]

Commercial television in the United Kingdom began in the mid-1950s when Parliament established the Independent Television Authority (ITA) on July 30, 1954. Other commercial television companies such as Thames Television, Associated-Rediffusion, London Weekend Television, Granada Television Network, and Channel 4 decided to work together to compete with the BBC for audience share. Jointly they own ITN, a profit-making news business.^[23] Part of ITN Source, one of the largest moving image libraries in the world, the Archive began in 1955 with the first ITN news program broadcast. In 1998, after housing ITN's news programs since 1955, the ITN Archive signed a deal to sell Reuters' news library. In 2002, ITN Archive began managing the Channel 4 Archive clip-sales business, and in 2003, it started marketing and managing the historic British Pathé film archive with footage dating back to 1896. Other deals benefiting the ITN Archive include the representation of Granada Television clips in 2003, the representation of U.S. Fox News and Fox Movietone archives in 2004 and becoming a key launch partner with Google Video in 2006.^[26] Researchers can search for and order footage to be used under a license agreement.^[27]

The National Television and Film Archive at the BFI, located in London, is another rich resource of British television programming, holding around 625,000 programs.^[28] Their television holdings are through donations and through various agreements with the broadcasters including Independent Television (ITV) and Channels 4 and 5. The Archive also selects examples of regional programs and has an access arrangement with the BBC in which researchers can view material produced by BBC1 and BBC2 since August 1990 and from BBC3 and BBC4 since their inception.^[29] The Archive offers a variety of services to researchers, both nationally and internationally, including a researchers' guide of film libraries and archives listings and a searchable film and television database.^[30]

The National Media Museum, located in Bradford, UK, is part of the National Museum of Science and Industry

(NMSI) Museums Group.^[31] The Television Collection represents the evolution of television production since the late nineteenth century to the present. Types of materials include television recorders, television cameras, and television receivers.^[32]

Japan

While Japanese experimental television began in 1939, World War II ended research until the early 1950s, which saw the beginnings of Nippon Hoso Kyokai (NHK) and Nippon Television (NTV). NHK, Japan's public broadcasting system, began in 1926 as a radio network. After World War II, the Occupation Authorities issued the Radio Law, the Broadcast Law, and the Radio Regulatory Commission Law, all to reduce government control over broadcasting. Due to these regulations, NHK is independent from the government and is mostly funded through consumer fees. Its programming, divided into two networks, includes news, cultural and entertainment programs on NHK Sogo, and educational programs on NHK Kyoiku.^[33] The Japanese network, NHK, established its archives in February 2003 in commemoration of the 50th anniversary of television in Japan. In its Tokyo headquarters, the NHK Archives has over 500,000 programs that visitors can view on-site.^[34]

Canada

The Canadian Broadcasting Company (CBC), a public network operating under a parliamentary mandate, has its archives in Toronto. These archives hold more than 70 years of radio and television history on millions of discs, tapes, films, photographs, written records, and computer files. Originally a low priority, the CBC gradually realized that archiving past material was worthwhile, especially after technology made production cheaper and storage easier.

The work of the archives staff includes the ongoing capture of new material, doing research and technical preparation for programming, and selling and sourcing of archival content to broadcasters and other third parties. The archives' first priority is the capture, cataloging, and storage of new material. The archive also tries to gain intellectual and physical control over its backlog of material.^[35]

Australia

The Australian Broadcasting Company archive materials are located in various repositories. The ABC Archives and Library Services serve the needs of ABC Radio, Television, and Multimedia as well as external customers worldwide. To this end, the Archive selects, catalogs, and preserves material representing an audiovisual record of Australian history.^[36–38]

Researchers can find additional Australian broadcasting material at the National Film and Sound Archive (NFSA) in Acton. The NFSA's mission is to collect, store, preserve, and make available Australia's audiovisual history.^[39] Through this mission, the NFSA supplies footage and recordings for use in television and radio productions. With expert technicians skilled in preservation practices, the NFSA transfers, duplicates, restores, and reformats materials in all formats.^[40]

SCOPE OF ACTIVITIES OF FILM AND BROADCAST ARCHIVES

Preservation of Audiovisual Material

Film

While digital formats are now the dominant mode of motion picture production, postproduction, distribution, and exhibition, analog formats continue to predominate in most film archives and may continue to do so for many years. Over the last 100 years many motion picture formats have been marketed, as new developments in film gauge, composition, and aspect ratios emerged. Flammable nitrate-based film, used for the first 50 years of commercial film production, was replaced in the mid-1950s by acetate "safety" film. (Note that nitrate was only used for 35 mm motion picture film, never for the amateur or semi-professional gauges of 8 or 16 mm film [Fig. 1].) There have been numerous color and sound systems over the decades as these technologies were engineered and perfected. Fortunately, for film archivists, the drive toward standardization spearheaded by the Society of Motion Picture Engineers (now the Society of Motion Picture and Television Engineers (SMPTE)) has resulted in relatively few modern analog motion picture formats currently in use (in comparison to the bewildering array of digital formats now available).^[41] Table 3 summarizes the most common analog film formats. Those readers interested in a concise introduction to film technology should consult Enticknap.^[42]

For most noncommercial film archives, as well as for many commercial ones interested in protecting their assets, preservation is seen as a core function. While archives focused on copying of decaying nitrate film to acetate in the early days as their primary preservation treatment, the emphasis for most archives now is on providing appropriate, secure storage facilities that control temperature and relative humidity, protect against damage from natural disaster and fire, and reduce airborne pollutants such as the acetic acid produced by the deteriorating acetate film. By placing collections in good storage facilities that slow down the rate of physical deterioration for motion picture film, archives can extend the life of their

Fig. 1 Reel of 16 mm motion picture film. The 16 mm format was commonly used for television production as well as government, business, medical, and industrial filmmaking from the 1930s through the 1980s until it was largely supplanted by videotape technology.
Source: Photograph courtesy of Tom Connors.

Table 3 Common analog film formats.

Gauge	Users	Bases
35 mm	Professional market	Cellulose nitrate (1894–1953) Cellulose diacetate (1909–1940s) Cellulose triacetate (1948–present) Polyester (1950s–present)
16 mm/Super 16	Professional, industrial, educational; also used by artists and amateur filmmakers	Cellulose acetate, various esters (16 mm: 1923–present; Super 16: 1971–present) Polyester (1950s–present)
8 mm/Super 8	Consumer market (amateur/home movies; small gauge enthusiasts)	Cellulose acetate, various esters (8 mm: 1932–present; Super 8: 1965–present)

collections and obtain a longer window for making preservation decisions.

Analog Audio and Videotape Materials

According to the organization Independent Media Arts Preservation (IMAP), electronic media is especially vulnerable because the short life expectancy of magnetic tape rules out its use as a permanent, archival storage medium.^[43] Additionally, most analog audio and video formats are already or close to becoming obsolete—tape formats, machine, computer hardware, and software are constantly being upgraded—making it difficult to maintain machines for playback of older media.^[43] The earliest videotape, the 2” Quadraplex, introduced in 1954, required large, compressed-air-driven machines that can only be run and maintained by engineers trained to operate them (Fig. 2). Later analog formats, such as ¾” U-matic, VHS, Betamax, and Betacam, each require their own machines, all of which are becoming increasingly rare and which do not read other formats (see Figs. 3 and 4). Though newer

digital formats such as Digital Betacam, DVCAM, and Digital 8 are recommended for preservation masters, these formats also have problems with tape stability and incompatibility with other formats. For an overview of videotape formats, see Tables 4 and 5.^[44]

Problems with magnetic tape as a storage medium include natural deterioration such as binder hydrolysis, also known as “sticky shed syndrome,” in which the tape’s binder coating absorbs moisture in high heat and humidity and leaves a gummy residue on the tape and machine surfaces.^[43] Signal loss is a common risk for analog formats. Signal loss can occur as a result of either physical damage to the tape or degradation of the tape components (most often the binder). Archivists are encouraged to reformat these tapes through expert vendors after cleaning and to rehouse originals in nonacidic, nonreactive containers.

Audio formats, both analog and digital, also have their preservation issues. Radio archives can have many formats including transcription discs dating from 1929, wire recordings from the 1930s, acetate-based magnetic recording tape dating from 1948, digital audiotape recordings

Fig. 2 Ampex 2 in. Quadruplex machine, located at the Library of Congress Packard Campus for Audio-Visual Conservation.

Fig. 3 One inch Type C videotape, developed by Ampex and Sony and used as a broadcasting standard from the late 1970s through the early 1990s, replaced the cumbersome 2 in. Quadruplex format.

Source: Photograph courtesy of Tom Connors.

Fig. 4 The family of Betacam products, including Betacam (1982), Betacam SP (1986), and Digital Betacam (1993), are all one-half inch in width. Tapes come in S and L sizes (Betacam videotape recorders accept both sizes, but Betacam cameras use the S size exclusively). The Superior Performance (SP) variety was the format of choice for preservation purposes for many years, although it is now considered to be an endangered format in the wake of Sony's decision in 2002 to cease production of recorders and players.

dating from 1962, audiocassettes dating from 1963, compact discs dating from 1983, and Super Audio CD (SACD) and streaming audio from 1999.^[45] These formats require compatible machines, some of which have become increasingly obsolete (see Figs. 4 and 5).^[46] The fragility of transcription discs, usually coated with lacquer or, during World War II, made of breakable glass, makes these materials particularly at risk and in need of reformatting.^[47]

Digital Formats

Preservation of digital audio has progressed significantly in the last 20 years. Echoing the transition to digital in audio production and distribution, archivists have embraced digital technology as the primary method to preserve audio for the future. As most analog audio formats have now become obsolete, with the exception of LP records, most archives have chosen to migrate their analog recordings on cylinders, discs, and magnetic tape to an uncompressed digital format such as Broadcast WAV for long-term preservation purposes.^[48] The significant storage requirements of uncompressed digital video have thus far hindered wide-scale adoption of digital formats as target preservation formats in the conversion of analog moving images to digital storage systems. The rapid decline of motion picture film manufacturing in the wake of transition to digital distribution and exhibition for most commercial film releases, combined with carrier degradation and obsolescence of most analog video formats, will hasten many archives' decision to migrate their significant analog film and video collections to digital formats.^[49,50] While the moving image archiving community still works

primarily with analog material, the influx of digital material has begun and most archives are grappling with a potential solution for long-term preservation of digitized and born-digital material.^[51]

Appraisal

Film

For many years, the appraisal of films was seen as an unusual, even dangerous, activity. Given the number of films lost due to deterioration or discarded by their owners when no longer profitable, early film archivists aimed to save as much as they could.^[52] While some archivists, such as Iris Barry, film curator at the Museum of Modern Art, were quite selective in what was chosen as part of the collection, other archivists preferred to “take the films now and ask questions later,” reserving judgment on films until further assessment of their value could be undertaken.^[53] The latter attitude toward appraisal often meant that collections grew beyond the capabilities of the facility and staff who worked at the archive. Even today, it is rare to find appraisal as part of the institutional mission and activities. An atypical example is films collected for the NARA, which are subject to the record retention and disposal schedules created for government agencies. Outside of such government archives, however, appraisal has rarely been formalized as an archival activity, and what little has been done has often been scattershot. Interestingly, some archives are more likely to be interested in monetary appraisal, for purposes of accepting a film collection from a private donor, than in an assessment of the material's archival values.^[53]

Radio

Sound archivists often acquire materials from collectors in an ad hoc fashion instead of based on a set records management schedule. As a result, they often have to weed out

unwanted materials to make a more cohesive collection. Due to limits on space, staffing, and finances, archives cannot be unlimited storehouses, keeping every sound recording in perpetuity. Those who advocate retention of all materials often forget that archivists do not have

Fig. 5 One-quarter inch magnetic audiotape, once considered the gold standard for preserving sound recordings, has been largely abandoned in favor of transfer to digital formats stored on high-density magnetic tape formats (such as LTO), hard drives, or secure servers.

Source: Photograph courtesy of Tom Connors.

unlimited time to go through hundreds of hours of material to appraise, process, and make it available for research. Unlike textual materials, audio recordings must be listened to in real time. The audiovisual archivist must use disciplined appraisal methods to keep materials selected in accordance with archival principles. If possible, the archivist should be involved in prearchival control by working with collectors to ensure that material is recorded on good quality audiotape to maintain minimum technical standards.

The basic principle of selection, which is a craft rather than an exact science or an art, is to preserve material with evidential or research value in order to ensure a balanced, representative collection relevant to the nature of the subject matter and the archive's purpose. Two types of selection processes, as defined by Rolf Schuursma, are coarse and fine mesh.^[54] With coarse selection, the archivist evaluates complete collections without investigating individual recordings. The result is a larger but less manageable collection, especially if there is little documentation.

With fine mesh selection, the archivist examines each recording, providing documentation and adequate cataloging. This selection type is good for material that enters the archives in small groups or singly. Another type of selection process, sampling, is especially useful for radio broadcasting material. One example, based on the policy of the Public Television Archive of PBS, has the archive keep the first, last, and representative episodes of a series. Radio archives also use this process to keep one news broadcast daily as the main broadcast. Material that is then weeded out is not always destroyed but may be stored elsewhere or offered to another archive.

Television

In 1995, NPBA curator Thomas Connors and then WGBH Archivist Mary Ide received a Bentley Fellowship to research appraisal standards for public television materials. In his article, "Appraising Public Television Programs: Toward an Interpretive and Comparative

Evaluation Model,” Connors offered a three-tiered ranking scheme to evaluate programs for preservation.^[10] For this scheme, the archivist would examine the following elements for each program: provenance, cost of retention, implications of selection decisions, reference potential, and critical values. The archivist would then rank the programs into three tiers. The first-tier programs would be reformatted for permanent retention. If resources become available, then the second-tier programs would be reformatted. Finally, the third-tier programs would be kept in their original format.

Approaching the appraisal question from the station’s point of view, Mary Ide and Leah Weisse described the retention criteria of the WGBH Media Archives and Preservation Center in their 2003 article “Developing Preservation Appraisal Criteria for a Public Broadcasting Station”.^[55] Every WGBH-produced program sent selected production elements, records, and multiple masters to the Archives. Soon, to save retention costs, the WGBH Archives began to implement a preservation selection standard in order to create a quality collection of program content. This production standard was based on four values: institutional, informational, reuse, and the cost of retention. For institutional values, the WGBH Archives kept track of the program category and genre to maintain a balanced selection as mandated in the WGBH mission statement. Thus, the Archives would describe programs by category such as humanities, music, or science and by genre such as documentary, public affairs, or instruction. Next, for informational values, the Archives looked at the level of cataloging, whether from the shot level by the production staff to descriptive video and closed-captioning after the production has finished. This information is useful for future research and reuse. Reusing a program also plays a factor as to whether it is worth preserving, as maintaining an archive of editorial content saves the station research time and money. Thus, the Archives work with both WGBH Enterprises and the Media Library to determine marketing possibility through possible footage sales. When the Archive has determined what to keep, the next value considered is the cost of retention. There, the Archives looks at such costs as tape transfers, storage, processing and cataloging masters for preservation, adding new catalog information to the Archives database, and the reshelving of newly dubbed material.

Cataloging and Description

Just as archivists need to preserve materials, they also need to know what they have. To reach this goal, the archivist describes the material and creates a record of who authored a work, its format, how many copies the archive has, the work’s value, and who owns the copyright. However, there are many challenges in cataloging and describing audiovisual media. Often, the media object

does not have accompanying labels and must be played in order to determine its contents. Due to the potential danger of damaging older audiovisual material by playing it, archivists often create an incomplete catalog record until they can make a preservation copy and can then update the record.

The organization and description of film and broadcast material has not followed the same path of standardization that helped librarians assume intellectual and physical control over library resources. Sound and moving image cataloging schemas often grew organically within institutions and corporations, with the primary goal of facilitating the retrieval of particular titles, broadcasts, or footage. The approach of a museum registrar describing a collection of avant-garde films was likely to be quite different from the method of a librarian cataloging outtakes for a stock footage house or an archivist organizing a set of corporate in-house productions. While some catalogers have adapted their descriptions to currently existing standards like Resource Description and Access (RDA), Machine-Readable Cataloging (MARC), and the Library of Congress Subject Headings (LCSH), others have created in-house rules for description and subject access.

Digitized and born-digital materials require new ways of cataloging and providing access to material through the use of metadata standards. Metadata, or data about data, helps describe, explain, and locate information about various types of textual and nontextual objects. The three types of metadata include descriptive, such as title, author, and keywords; structural, such as the information about how the parts of complex digital objects relate to one another, for example, the information needed to order individual shots and synchronize picture and soundtrack to create audio or video news stories; and administrative, such as access information and creation information.^[56]

Audiovisual archivists have developed or adapted several metadata standards to meet the functional requirements of describing, preserving, and providing access to moving images. Some archives, particularly those within library organizations, have tailored the Metadata Object Description Schema (MODS) standard, an XML-based derivative of MARC, to describe audiovisual media in collections. For those working outside the library community, other standards have been developed to address the particular needs of moving images. The PBCore data standard was originally developed for the public broadcasting community but has been adopted by other organizations with audiovisual collections that are looking for a way to describe their media items’ intellectual content, property rights, and formats. The PBCore standard is based on the Dublin Core Metadata Element Set, with added fields that are specific to the requirements of describing audiovisual media.^[57] Audiovisual archivists have also developed application profiles for media description that employ elements from metadata standards such as the Metadata Encoding and Transmission Standard (METS), which is

used for bundling and encoding descriptive, administrative, and structural metadata regarding objects within a digital library, and the Preservation Metadata: Implementation Strategies standard (PREMIS), which supports the long-term preservation of digital objects. Other archivists may adopt metadata standards used by the commercial motion picture and television community that are more appropriate for materials in production environments, including MPEG-7 (the Multimedia Content Description Interface), MPEG-21 (a standard for expressing rights, permissions, and restrictions on the use of moving images and sound), and SMPTE standards (including the SMPTE Data Dictionary and the MXF container format for digital audio and video media, which can record various types of metadata in its file header).^[58]

Audiovisual Cataloging Resources

A number of cataloging resources have emerged that take existing sets of rules or headings and tailor them to the needs of moving image and sound description. One such rule set is the *Archival Moving Image Materials (AMIM)* standard, which is based on the *Anglo-American Cataloguing Rules (AACR)*.^[59] Another rule set is the *FIAF Moving Image Cataloguing Manual*, developed by representatives of institutional members of the FIAF. The FIAF rules have recently been revised to reflect the Functional Requirements for Bibliographic Records (FBRR) model and aim to be compatible with multiple metadata schemas such as Dublin Core and MARC.^[60]

While catalogers have often taken terms from LCSH to assign indexing terms, particularly for nonfiction films, the Moving Image Genre-Form Guide (MIGFG) term list was specifically created to give film seekers access to films by type or category and often is used to supplement LCSH.^[61] Similarly, the Radio Form/Genre Terms Guide (RADFG) provides a list of subject headings for sound archivists cataloging such material.^[62]

For materials such as stock footage and news stories, which often lack the hallmarks of authorship such as formal titles, catalogers have often developed separate databases using software like FileMaker Pro or Microsoft Access and created their own thesauri specific to the collection at hand, rather than attempt to integrate records of moving image resources with preexisting catalogs. While the variety of resources created by moving image catalogers often served the internal needs of the organization well, such homegrown systems were rarely interoperable with other systems.

Access

Whether the material is textual or audiovisual, researchers want access to it. Preservation and cataloging are key methods for providing this access. However, the Library of Congress television and video preservation report notes

that obstacles to access include “. . . underfunding in public archives, lack of descriptive cataloging and reference copies, copyright interests, and very restrictive usage policies” (p. 9).^[17] Other problems, as noted in the Council on Library and Information Resources (CLIR) 2004 report, *Survey of the State of Audio Collections in Academic Libraries*, include physical deterioration, lack of staff, intellectual property rights, and space problems.^[63]

On-site

While audiovisual archives, particularly those found in public institutions, have always had the capability to provide on-site access to materials in their collections, preservation imperatives and copyright restrictions have often made it difficult or impossible for institutions to lend films to users for off-site use. Larger archives had the resources to create study centers, which users could visit for the purposes of requesting titles to view that have been transferred to CD, video, or DVD, while smaller archives must often make do with a few listening or viewing stations. One problem for many archives is the inability to provide even on-site access to users, either because they lack the proper equipment to view material or because they do not want to risk damage to fragile, often deteriorating, material by screening it for users before it has been transferred to a more stable format.

Online

With recent advances in audio and moving image digitization and streaming technologies, many archives are exploring the Internet’s promise for increasing access to collections and reaching new users who are unable to travel to the archive to listen to recordings or view films and videos. While copyright restrictions still limit archives’ ability to provide access to many materials in the online environment, for those films and broadcasts that are in the public domain or for which archives have the rights to distribute, archives can now provide digitized versions of sound recordings, films, and videos for downloading or streaming. Users can integrate digital audio and moving images into new works or research much more easily than before. The explosion in video sharing services such as YouTube and Vimeo also offers a new template for archives to consider when designing sites for accessing material—users can now provide valuable information through tagging and commenting activities that may enrich the catalog.^[64]

Projection of Motion Picture Film

The lure of online access has the unfortunate side effect of overshadowing an important mode of access to analog film materials: presentation through projection. In the wake of the digital transition, the number of working

projectors for the 35 mm format has dwindled rapidly. The National Association of Theatre Owners reported that conversion of motion picture theaters to digital projection had occurred for approximately 94% of all commercial venues in the United States by May 2014.^[65] In the current environment, where most theaters have abandoned the 35 mm format, specialized venues such as museums, archives, and universities with large collections of features on 16 and 35 mm may be the only locations where users will be able to see film as a projected medium.^[42]

The 16 mm format, once the mainstay for schools, churches, nonprofit organizations, and others to show educational, industrial, amateur, and other types of non-theatrical films, has largely been abandoned in the wake of video, DVD, and other digital forms of exhibition. Used equipment for 16 mm projection has been widely available in the past, although the challenges of maintaining such equipment and the preference for newer formats of such material by most users are the reasons why most institutions have jettisoned much of their 16 mm collections (buying DVD replacements where available, or transferring them to a newer format if no DVD replacement can be found).^[66]

The 8 mm and the Super 8 formats are no longer used by most amateur and home moviemakers, who long ago adopted video formats (initially flocking to the analog video formats first introduced in the 1980s and, more recently, to digital video formats). These small gauge film formats continue to have a fan base, however, with enthusiasts such as experimental filmmakers and archivists. While these collections are found much more often in personal collections than in institutional settings, the

rediscovery and celebration of small gauge films by organizations such as Home Movie Day means that more and more of this valuable material may find its way into archives and museums.^[67]

ISSUES AND TRENDS AFFECTING FILM AND BROADCAST ARCHIVE WORK

Developing Digital Archiving Systems to Support Production, Access, and Storage

As the film and broadcast industries continue to adopt new modes of production, distribution, and exhibition, archives must prepare themselves to care for the new formats generated by production companies, artists, researchers, and amateur filmmakers. The digital formats of today will challenge archivists to develop solutions to problems such as rapid media and format obsolescence, restrictive copyright laws hindering preservation and access imperatives, and creating preservation-ready repositories for reliable and affordable long-term storage of digital moving images (Fig. 6).

While many archives have focused attention on obtaining appropriate storage facilities for their analog collections and maintaining machines to access film and video elements, they also have been contemplating requirements for accessioning, maintaining, and making accessible digital moving image collections. While media asset management systems predominate in commercial organizations where systems must support production environments, many noncommercial organizations are

Fig. 6 DAT uses 4 mm tape and its dimensions are roughly half that of the Philips compact audiocassette. Its recording quality represented a great improvement over analog magnetic tape; however, it has been used largely by professionals rather than being a consumer format. Sony ceased production of DAT recorders in 2005, which adds it to the long list of obsolete magnetic tape formats.

choosing to construct digital storage repositories according to the Open Archival Information System (OAIS) model in order to meet needs to preserve the content, integrity, and authenticity of moving image material and manage the migration of files in obsolete formats to current formats. Specific features that are desired of these new preservation-oriented systems include support of on- and off-site ingest; centralized metadata creation and maintenance (where metadata can be acquired throughout production workflows, as well as in later assessment and cataloging workflows); automated migration of analog and digital files to uncompressed, nonproprietary formats; hierarchical storage management; selection criteria for long-term preservation; quality control; and environmental control for data storage systems. Larger organizations with significant resources may prefer to build customized in-house systems, but other smaller organizations are exploring the adoption of open-source solutions in whole or in part to accomplish preservation and access goals. The Hydra repository and associated software components is one such open-source solution being employed by organizations such as WGBH, Indiana University Libraries, Stanford University Libraries, and Northwestern University Library.^[68]

Copyright Legislation

Copyright legislation such as the Copyright Term Extension Act (CTEA) of 1998 (Public Law 105–298) and the Digital Millennium Copyright Act (DCMA) of 1998 (Public Law 105–304) often restrict the ability of archives to fulfill their missions of preservation and access, particularly those noncommercial archives holding large quantities of copyrighted material still considered to have commercial value. The CTEA has ensured that most material from the sound era of motion pictures remains under copyright (except for those titles whose copyright lapsed back when the United States required copyrights to be renewed for continued protection). For films still under copyright, archives cannot distribute them freely (access is limited to on-site viewing), must pay copyright owners for any public exhibitions, and have limited powers to make copies of them for preservation purposes.

The DCMA further limits archives in achieving preservation goals by forbidding them from circumventing mechanisms meant to protect copyrighted material such as digital rights management (DRM) systems and encoding and encryption schemas, in order to make copies for preservation purposes. While archivists have lobbied the Copyright Office to provide exemptions for preservation work, no rulings from the Office have yet given archivists the power to do so. Some hope may be drawn from a 2006 exemption that allows university educators to rip clips from DVDs and other digital files in order to make compilations for use in the classroom as part of film or media studies courses.^[69]

In certain motion picture genres, such as silent, educational, and industrial films, many titles have fallen into the public domain or are no longer cared for by their owners, who may no longer be in business. These films have been dubbed “orphans” by the moving image archiving community, and interest in protecting and preserving them has grown exponentially in the last decade, particularly as federal grant programs have targeted them as strong candidates for preservation funding. The Orphans Film Symposium, first established in 1999 by Dan Streible and fellow enthusiasts (known as orphanistas), has become the premier event for archivists, scholars, educators, and others eager to celebrate these films.^[70]

Attempts to remedy the problem of copyright limbo for orphan works through the introduction of legislation to the U.S. Congress in 2006 failed due to opposition by photographers, illustrators, and textile designers. Since then, the U.S. Copyright Office has been investigating this issue through studies and public comment periods; these activities may eventually lead to some sort of exemption to the current copyright law.^[71]

The issue of copyright is also important in the field of broadcast archives. The Copyright Law of 1976 encouraged scholarly use of audiovisual material by permitting off-air taping for educational purposes.^[46] Under the law, retention of off-air videotapes for classroom use is limited to 45 calendar days and further use requires a license from the copyright owner. However, unlike the American Society of Composers, Authors, and Publishers (ASCAP), there is no copyright clearinghouse, and researchers thus have problems finding accurate copyright information on older programs. The 1997 Library of Congress report on television and video preservation recommends that interested parties discuss issues such as revising fair use guidelines and policies for off-air recording, especially concerning programs without clearly identifiable copyright ownership.^[17]

Copyright limitations affect access to materials both on-site and remotely. For example, Vanderbilt Television News Archive provides limited access to its collection via streaming video due to copyright consideration. While it makes dubs of news programs on request, the archive considers the tapes to be loans.^[13] Another example is the Paley Center for Media, which encourages researchers to view programs on-site. The Paley Center does not have any rights to the tapes that were donated to the Center, which are “only to be viewed or listened to in the Paley Center by the general public.”^[72]

For government collections, deposit laws vary from country to country and are not always equally applied. For example, the collections in the Library of Congress Television Archive offer a broad but incomplete view of television history. Reasons for incomplete runs of television series include the Library’s earlier practices of selectively keeping deposit copies for copyright protection, earlier producers deciding not to register their programs, problems with legal definitions of publication, and the

underestimation of broadcast recordings as a scholarly resource. In 1966, the Motion Picture Section's reference staff started answering television questions, and the acquisition of programs began to expand.^[73]

Building New Storage Facilities for Audiovisual Media

In the last 20 years, many archives have focused on the construction of the new storage facilities for their collections, in an effort to prolong the life span of fragile film and video material in danger of decay. The Museum of Modern Art in New York completed the Celeste Bartos Film Preservation Center in Hamlin, Pennsylvania, in 1996; Northeast Historic Film, a small archive in Bucksport, Maine, built a cold storage facility in 2003 that rents space to other institutions in the New England area seeking a place to store their moving images; the Library of Congress built the National Audio-Visual Conservation Center in Culpeper, Virginia (which opened in 2006 and includes facilities for storage of digital moving images as well as analog film and video elements); and the UCLA Film & Television Archive relocated all conservation activities to a new facility in Santa Clarita, California in 2015 (Fig. 7).^[74–77]

Other smaller collections found within larger institutions may also be benefiting from trends of academic libraries such as the University of Toronto, the University of Pittsburgh, the University of California, Berkeley, the Harry Ransom Center at the University of Texas at Austin, and, the University of Texas at Arlington, to create cold storage facilities to house those types of photographic and magnetic media that require colder temperatures and lower relative humidity than print collections.^[78]

Funding for Audiovisual Preservation

Funding for Film Preservation

In the last two decades, the sources of funding to support film preservation activities have changed significantly.

Whereas the primary funding source in the 1970s and 1980s was the federally funded American Film Institute-National Endowment for the Arts (AFI-NEA) grant program, cuts in federal funding to the NEA in 1994 led to the discontinuation of this program. In 1997 the National Film Preservation Foundation (NFPF) was established by the National Film Preservation Act of 1996. As a public charity, its goals are to support preservation of orphan films by facilitating fundraising from individuals, organizations, and corporations and encouraging in-kind contributions of goods and services from laboratories and suppliers of preservation materials.^[79] To date, the NFPF has contributed to the preservation of over 2,000 films.^[80] Other federal grant sources funding film preservation have included the National Endowment for the Humanities (NEH) and the National Historic Publications and Records Commission (NHPRC).

Archives have come to rely increasingly on the donations from private individuals and foundations in recent years to fund capital expenditures, such as new storage facilities and study centers, or to defray costs of digitization and access projects. The Film Foundation, the David and Lucile Packard Foundation, and the IBM Corporation have supported major projects at film archives in recent years.^[81,82] Archives have worked together with studio copyright owners such as Sony, Paramount, and Walt Disney, which often contribute funds for laboratory services and lend production elements to assist with preservation projects.

Funding for Television and Video Preservation

The Library of Congress television preservation report notes that often funding of television and video preservation has been inadequate, with some exceptions. Many foundations reject video preservation grant applications because videotape is perceived as inadequate for long-term preservation. While federal agencies such as the NHPRC and the NEH have awarded funds to public archives primarily to improve access, there has been little

Fig. 7 Exterior of the Packard Campus for Audio-Visual Conservation.
Source: Photograph courtesy of the Library of Congress.

coordination and communication among the different agencies.^[17]

Based on the recommendations of the Library of Congress report, the National Television and Video Preservation Foundation (NTVPF) was created to raise private funds and provide grants for preservation projects in institutions with television and videotape collections.^[83] Since its inception, NTVPF has awarded grants for projects such as ten hours of videotapes from the Experimental Television Center in 2004.^[84] NTVPF is currently dormant, with no new grants being announced in the last decade. The future of this foundation is not clear at the time of this writing, unfortunately.

The American Archive of Public Broadcasting is another funded television preservation project. In 2007, the Corporation for Public Broadcasting (CPB) started an inventory of public media content from participating stations resulting in over two million records representing a wide range of media content including complete programs, unedited interviews, and live music sessions. The first 40,000 hours of content digitized for permanent preservation and public access was funded by CPB.^[85] The American Archive of Public Broadcasting, instituted in 2013, continues to preserve public television programming through funding from CPB.^[86]

Funding for Radio Preservation

In the area of radio, funding for preservation comes primarily from the following sources. The GRAMMY Foundation awards grants to archives for planning, assessment, consultation, or implementation of preservation projects.^[87] One prominent recipient of preservation grants from the GRAMMY Foundation is the Pacifica Radio Archive's weekly radio show *From the Vault*.^[88] Other funding sources for preservation and access have come from the NEH's Preservation and Access program and the Save America's Treasures program (cosponsored over the years by various government and civilian agencies including the National Park Service (NPS), the National Trust for Historic Preservation, NEA, and the Institute of Museum and Library Services (IMLS)), which have also made grants relating to preservation and access projects.^[89–92]

Education and Professionalization Opportunities for Film and Broadcast Archivists

Graduate Programs in Moving Image Preservation and Archiving

The Library of Congress report *Redefining Film Preservation* strongly urged the moving image archiving community to develop educational programs at the graduate level to produce archivists trained to care for the burgeoning collections of analog and digital material in U.S. repositories.^[93] Within a decade, several programs had been

established, including the L. Jeffrey Selznick School of Film Preservation at the George Eastman House (established in 1996; the School began to offer a joint M.A. degree combined with a Certificate in Film Preservation with the University of Rochester in 2005); the M.A. in Moving Image Archive Studies at the University of California, Los Angeles (2002); and the Moving Image Archiving Program at New York University (2003). Internationally, several programs are available in Canada, Europe, and Australia. Additionally, moving image archiving courses have been added to the curricula at several library and information science (LIS) programs in the United States, making educational opportunities much more widely available. The Library of Congress maintains a current list of moving image archiving educational opportunities available both in the United States and abroad.^[94]

Similar recommendations have been made to train a new generation of sound archivists.^[95] These suggestions have yet to result in many formal educational training opportunities at the graduate level, unfortunately. Several LIS schools have begun to offer electives in sound archiving and reformatting, including the University of Texas at Austin and UCLA, which have regularly offered courses in this area.

Moving Image and Recorded Sound Archives Associations

In North America, the primary professional association serving the moving image archiving community is the Association of Moving Image Archivists (AMIA).^[96] As noted earlier, FIAF also plays an important role; however, it must be acknowledged that only institutions can be members of FIAF, while AMIA has both individual and institutional membership, which allows it to facilitate communication among archivists more directly than FIAF. For sound archivists, the national organization that supports the profession is the Association of Recorded Sound Collections (ARSC).^[97] Other international associations that provide leadership in the field include the Southeast Asia-Pacific Audiovisual Archive Association (SEAPAVAA), the International Association of Sound and Audiovisual Archives (IASA), the International Federation of Television Archives (IFTA/FIAT), the International Council on Archives (ICA), and the International Federation of Library Associations and Institutions (IFLA). Many of these organizations offer opportunities for continuing education through their annual conferences, particularly AMIA and ARSC. FIAF holds a Summer School for training film archivists every other year as well.

CONCLUSION

To summarize, the authors defined the scope, mission, and activities of film and broadcast archives, focusing

particularly on archival functions including preservation, appraisal, description, and access to moving image and sound material.

Several important factors emerged as critical issues for film and broadcast archives. First, film and broadcast material requires extensive description, which is not fully supported by traditional library descriptive tools such as Resource Description and Access or MARC. Metadata standards developed or revised specifically to address preservation and access activities, particularly for newer digital formats, have been developed or adapted by the film and broadcast archiving communities, including PREMIS, PBCore, the FIAF Moving Image Cataloging Manual, MXF, MPEG-7, and MPEG-21 to provide archivists with opportunities to make full descriptions of legacy and digital formats. Adoption of these standards will facilitate interoperability among film and broadcast archive repositories, and may lead to increased information sharing among archives and facilitate searching across collections.

Second, appraisal methods for audiovisual archives must continue to be developed and refined to establish best practices for selecting film and broadcast materials for long-term retention. Models developed in the area of appraisal for television broadcast material should be tested for other audiovisual media and digital materials.

Third, preservation concerns such as format obsolescence, as well as copyright considerations, can often complicate efforts to provide access to audiovisual archives. Archives will need to be proactive in advancing archival interests in the areas of copyright reform and development of new formats suitable for long-term storage of audiovisual media.

Finally, audiovisual archives, while continuing to emphasize the importance of caring for legacy formats, must now deal directly with the effects of the digital transition and its accompanying new paradigms for preservation and access. These new directions and responsibilities require financial support both from within their institutions and from external sources. Archivists will need to lobby their own organizations and government agencies for the continued support of funding for preservation and access activities, as digital repositories are designed and launched to care for moving image and sound archives into the future.

Film Archiving: History

Steve Ricci

Department of Information Studies/Film and Television, University of California–Los Angeles,
Los Angeles, California, U.S.A.

Abstract

This entry provides an overview of the evolution of motion picture archiving from its beginnings as an uncoordinated set of craft-oriented skills to its modern status as a profession. It discusses the role of the profession's major historical associations including the International Federation of Film Archives, the American Film Institute, the Library of Congress, and the Association of Moving Image Archivists.

This entry retraces the evolution of the field of motion picture archiving in order to provide the cultural and philosophical background to the extraordinary practical challenges that public-sector archives currently face. The two most useful books on the history of film preservation are Anthony Slide's *Nitrate Won't Wait* (Jefferson, North Carolina: McFarland, 2000) and Penelope Huston's *Keepers of the Frame* (London: British Film Institute, 1984). While Slide focuses on the major film archives in the United States, Huston concentrates on the large international institutions. Around the world, only 15%, at best, of all silent films survive. This means that almost 90% of what was screened during the first 30 years of cinema history cannot be seen by today's audiences. It is estimated that roughly half of the 21,000 feature films made in America prior to 1950 have been lost. If we then consider that much of what actually remains suffers from general wear and tear, color fading, deep scratches, shrinkage, and sprocket damage, and that only a small percentage of the extant films have been professionally restored and preserved, the picture is perhaps as bleak as it is barren. Although precise statistics vary somewhat, most estimates already tell us that significant moving image inventories are lost. Author Frank Thompson estimates the percentage of lost silent films at 80%.^[1] In the documentary *Keepers of the Frame* (Produced by Randy Gitsch, 1999), the estimated loss is 90%.

According to Penelope Houston, "it is generally assumed that some 75–80% of all silent cinema has been lost, most of it gone beyond recall unless caches still exist in the unexplored recesses of the archives or in the holdings of private collectors"—*Keepers of the Frame: The Film Archives* (London: British Film Institute, 1994). Moving Image Collections asserts that "only 10% of pre-1929 films survive."

The "Silent Era" Web site states that "educated guesses estimate that only 10–15% of the films made during the silent era survive today."^[2]

Exactly how much of America's film production has already been lost remains difficult to say. The most

familiar statistic, which has attained its authority primarily through repetition, is that we have lost 50% of all titles produced before 1950.^[6] This estimate may not be inaccurate so long as one qualifies it in three ways. First, it would apply only to full-length fiction films. Anecdotal evidence suggests that survival rates for other film types, even major studio newsreels and shorts, are lower. Second, among those studio features, there is a sharp break in survival rates at 1929, the year that sound film became the industry standard. Features of the 1930s have been recently documented to survive at a rate of no less than 80%, probably closer to 90%.^[7] However, fewer than 20% of the features of the 1920s survive in complete form; for features of the 1910s, the survival rate falls to slightly above 10% (and those in copies generally made from projection prints, not negatives, which are almost entirely lost)...Third and last, the familiarity of that 50%-before-1950 statistic also implies, by omission, that there are few preservation problems with films produced after that year—something which is not the case, as will be discussed (p. 56).^[3]

Historical memory of the world's moving image heritage is incomplete in three profound ways. Many films are permanently lost. Much of what remains is in immediate need of archival attention, and some of these films may never be able to be restored to an integral state. Even after the remaining titles have been repaired or reconstructed, it is extremely rare that these works can be exhibited to the public in a manner that even remotely resembles their original presentations.

Contemporary moving image archives, particularly in the public sector, face unprecedented practical challenges and a new set of opportunities. On the one hand, the soon-to-be expected disappearance of duplicating stocks constitutes a new threat to the long-term preservation of moving images on film. The major manufacturers of photographic raw stock have, over time, introduced, replaced, or simply discontinued numerous types of negative, reversal, and print stocks. For example, many of the 16 mm color reversal stocks, which were once the medium of choice for

television news films, are no longer available. Starting in the early 1990s, just as announcements began to appear about the anticipated deployment of digital cinema projection and distribution, Kodak significantly reduced its budget for research and development of new film stocks. These reductions certainly reflected the wide-spread transition from consumer still photography to digital cameras. One of the more troubling developments, however, is that newer moving image stocks do not accurately reproduce the visual qualities of Kodak's earlier products. This most recent technical problem represents potential loss that could far exceed the combined effects of nitrate and acetate deterioration. These two forms of chemical deterioration, which progressively destroy the film emulsion and/or its base, are responsible for the greatest loss of legacy films from the history of cinema. Cellulose nitrate was the dominant 35 mm film stock until the early 1950s until it was replaced first by cellulose acetate and then by polyester stocks. The latter types are generically referred to as "safety" film. What becomes of the millions of hours of unprotected archival footage when the ability to accurately copy film to film disappears? In 1993, it was estimated that 97 million feet of unique nitrate film footage, held in tax-exempt archives, was yet to be preserved. This estimate is even more staggering if we consider that a good portion of the original film-to-film duplications were done very quickly, and that current laboratory techniques have significantly improved. In other words, much of what was accomplished in the modern archival era needs to be redone.

On the other hand, new technologies may constitute new opportunities for the acquisition, preservation, and documentation of moving images. The technical capabilities of a digital future are regularly described as virtually limitless, unchained by the scarcity of time or material resources. Although it may be too early to assess precisely the long-term effect that these technologies (DVD, High Definition Television, Internet) will have upon moving image culture, they will certainly provoke intriguing ethical and theoretical questions. Given the vertiginous pace at which post-production technologies and new delivery platforms are evolving, the vital role of public-sector archives as agencies for historical memory will undergo a paradigmatic shift. Kay Hoffman has suggested that these changes are as significant as the most significant historical upheaval in all of cinema history:

The fundamental consequences of digitalization for movie production, post-production, and distribution can only be compared with the sea change brought about by the transition from silent to sound film at the end of the 1920s.^[4]

In comparison to traditional records and document-based archives, moving image archiving is a recent phenomenon. Its first formal association came only in 1938 with the establishment of the International Federation of Film

Archives (FIAF). On the one hand, this relatively new field does share many of the core functions of traditional archives, including collection development, preservation, documentation, and access. On the other hand, it diverges from these traditional archival institutions given the priority it has historically assigned to both the restoration and exhibition of archival materials. For example, the first lines of FIAF's Web site emphasize the importance of exhibition as part of its core mission: "... the world's leading archives whose purpose has always been to ensure the proper preservation and showing of motion pictures."^[5]

In contrast, the welcoming message to the International Council on Archives' Web site instead emphasizes key terms such as evidence, memory, and records. "Archives, by providing evidence of human actions and transactions, underlie the rights of individuals and of states, and are fundamental to democracy and good governance. Archives safeguard the memory of mankind by preserving records of its past."^[6]

Moving image archives also confront special challenges, perhaps shared only by photographic archives, generated by the complex question of what constitutes "any" original item. Throughout their entire history, moving images have generally been manifested in works existing in multiple copies, in multiple versions, and often in multiple physical formats. Moreover, the very separations between a work's carrier and its message, between its material status and its presentation, between structure and event, require additional attention to each and every level of archival practice. As we will discuss later on, these unique characteristics are both practical and philosophical in nature.

Although the field of moving image archiving has a comparatively short history, it has already moved through several distinct phases: 1) 1938–WWII: the early years of FIAF; 2) 1946–1970: preservation reigns; "Nitrate Won't Wait"; 3) 1970–present: the craft becomes a profession (AMIA) the era of Access. The mass circulation of moving images was a distinctive phenomenon of the twentieth century. Moving image media have been subject to a particularly accelerated rate of technological and cultural change. Precisely because of this accelerated evolution we can already point to at least three significant historical benchmarks or phases. Each of these phases was characterized by a substantial reconceptualization of some of the field's core goals and methods.

Archiving motion pictures has been practiced and discussed since almost the birth of the cinema itself. As early as 1898, photographer and documentarian Boleslaw Matuszewski, in his often cited essay *A New Source of History*, called for the creation of a proto-archive, a "Depository of Historical Cinematography." Matuszewski argued that the value of such an enterprise was found in cinema's "unique" ability to record history. "The cinematographe does not perhaps show history in its complete

form, but what it does show is indubitable and constitutes absolute truth. . . . It is an eyewitness par excellence, reliable and infallible.”^[7] From the time of this clarion call until the establishment of FIAF in 1938, it would be difficult to describe either a systematic response to Matuszewski or a system of shared practices codified by archival groups or associations. It is true, however, that during this pre-history, several major archival institutions began to operate, including the Imperial War Museum (1917), the Academy of Motion Picture Arts and Sciences (1927), the British Film Institute/National Film Library (1933) (For a detailed discussion on the evolution of the British Film Institute’s archival operations, see Dupin),^[8] the Film Library of the Museum of Modern Art (1935), and the Cinémathèque Française (1935). But it was only with FIAF that the loosely affiliated, individual archives made efforts toward establishing “universal” codes of conduct, and thus advanced toward the transformation of independent national archives into an international network with shared goals.

These initial efforts were characterized by two dominant philosophical orientations. On the one hand, some archives (most notably the Cinémathèque Française under Henri Langlois) concentrated on the exhibition of films as works of art. On the other hand, the British Film Institute (under Ernst Lindgren) focused almost exclusively on the long-term preservation and cataloging of its collections. Although it led to numerous internal battles, this foundational contradiction went unresolved, philosophically and practically, until the late 1970s. Despite the various maneuvers carried out by the field’s charismatic figures, FIAF’s inability to arrive at standards needed to define archiving as a profession of consistent practices was inextricably linked to Cold War tensions between its member nations. For decades, the Association’s Western-nation members were concerned about the potentially disproportionate influence that Soviet-block institutions might exert on international cultural policy. Thus, FIAF’s extraordinarily detailed statutes and rules effectively sought to achieve a political stalemate on many archival issues in light of the external Cold War political tensions.

Remarkably, the philosophical tension between “preservation” and “exhibition” would not be undone until FIAF’s Lisbon Congress in 1989. The event, entitled “Rediscovering the Role of Film Archives: To Preserve and to Show,” crystallized growing consensus over the rights (actually, the “duty” and obligations) of professional archives with respect to the exhibition of films. Under the umbrella of various publications and manifestos, this particular historical turn was expressed by the capstone mantra “To Preserve, To Show.” Public exhibition was thus recast as an organic result of the preservation mandate and accorded equal legitimacy and validation in the ideology of the Federation. Significantly, the new episteme led to a general liberalization of FIAF’s statutes and rules. As the Cold War’s cultural stalemate dissolved,

reforms within FIAF resulted in the admission of regional institutions, archives which prominently featured nonfiction materials, and, particularly, archives from the developing world.

During this first historical phase, a number of public-sector archives began to operate in the United States. Long before the advent of the American Film Institute (AFI) these had evolved into serious film preservation institutions. However, a common genealogy of the archival profession can be charted in relationship to the AFI, which had engaged in archival activities from almost its inception in 1967. Although the AFI had formally administered National Endowment for the Arts (NEA) preservation funds starting in 1971, it would not be until 1979 that the program would achieve a measure of budgetary and policy autonomy from the AFI’s traditional commitment to its film school. In these “early” years, funding was devoted to the acquisition and preservation of silent films and was dispensed to only a few of the country’s larger archives. From 1979 to 1982, 53% of the AFI/NEA funds went to silent film preservation and approximately 87% of the total was distributed to three nonprofit archives: the Museum of Modern Art, George Eastman House, and UCLA Film and Television Archive. During these years, the Motion Picture and Sound Recording Branch of the Library of Congress duplicated hundreds of American film titles. But, it too is an agency of the federal government, the Library was ineligible to receive NEA funding.^[9]

The decade of the 1970s witnessed the rapid expansion in public-sector archives and the birth of the modern archival movement in the United States. During this brief period of time, the tax-exempt archives vastly enlarged their holdings by acquiring studio collections (nitrate original negatives, fine grain masters, and prints) of classical “Hollywood” feature films that the major film studios were about to destroy. For a number of reasons, the establishment of the National Center for Film and Video Preservation in 1984 (the NCFVP at the AFI) was the apex of this evolution. Under the ubiquitous slogan of “nitrate won’t wait,” the cause of film preservation gained culture-wide visibility and film archiving made significant progress in its professional standing. Interestingly, Robert Rosen, the director of UCLA’s Film and Television Archive (who also served as the first director of the NCFVP) has referred retrospectively to the period leading up to the Center as the “buccaneer” years of film archiving.^[10] Not only would the NCFVP come to serve as the secretariat for the nascent Association of Moving Image Archivists (AMIA), it revitalized an AFI project to build a complete catalog of American Motion Pictures and established the National Moving Image Database (NAMID). Although the NAMID project would eventually be commercialized by the AFI, it was a significant step toward conceptualizing the totality of the archival field insofar as it was designed to acquire and share holdings

information for the totality of archival materials held in both the private and public repositories.

It is important to point out that the evolution of the field took place neither in a cultural vacuum nor only on a national level. One of the chief public voices in support of both archival practice and discourses on their importance came from the scholarly world and specifically from cultural and media historians. The cultural corollary for the birth of the modern archival movement was most clearly in evidence at FIAF's Brighton Congress in 1978. The Congress symposium focused specifically on newly restored films from the period 1900 to 1906. In addition to representatives of archives from around the world, Brighton also welcomed a new generation of scholars who would soon play a central role in the development of film education both in the United States and abroad, including Richard Abel, Robert Allen, Andre Gaudreault, Tom Gunning, Miriam Hansen, Charlie Musser, and Janet Staiger. In a special section of *Cinema Journal* dedicated to the "historical turn" in film studies, Musser described this evolution as a "...new integration of academic and archive-based history and fostered tendencies that contributed to the formulation of a new historiography." One of the most fundamental changes involved a new approach or attitude toward the subject.^[11]

Since this rapprochement, if not partnership between archivists (as custodians of history) and scholars (as writers of history), other significant forces have come into play.

CONCLUSIONS

Two benchmarks which characterize the contemporary moving image archive field in the public sector are the arrival of new digital technologies and the establishment of graduate-level degree programs in moving image archiving (at UCLA, NYU, and the University of Amsterdam). Paradoxically, the added archival capabilities offered by the new technologies only increase the need for additional advanced training of new generations of archivist. Although the new delivery platforms (such as DVDs, Blu-Ray, and the Internet) increase the professions capability to provide access to its collections, the exponential growth in content far exceeds the public sector's ability to serve as professional repositories.

The establishment of the AMIA in 1991 expressed both the need to codify professional behavior and a fundamental shift toward democracy within the field. A particularly good example is AMIA's MIC project, an attempt to provide a common portal for the cataloging of moving image collections.^[12] As a membership-based organization, AMIA accepts archivists from across the entire spectrum of archive types and passions. Whereas participation within FIAF is limited to institutional members, literally anyone can join AMIA. Furthermore, this "structural" democracy ignores the distinction between

private and public sectors, thereby theoretically narrowing the hierarchical and economical divisions between professionals. Even FIAF, which for decades had maintained hierarchical distinctions between types of members (full, associate, provisional) has in recent years sought to stimulate participation by moving away from its historically restrictive membership rules to a more open code of ethics in 1999. FIAF's code was constructed in part because the Association found it difficult to actually enforce certain aspects of its membership rules. Adherence to the Code, however, is now a precondition of membership.

Benefiting, in some cases, from the lessons learned by other archival traditions, film archiving, in its relatively recent move toward professionalism, has also recently placed increased importance on the issue of access to archival resources. Key benchmarks include, by the late 1980s, both the Motion Picture and Sound Recording Branch of the Library of Congress and the UCLA Film and Television Archive placing extensive information about their holdings online. For decades, public-sector archives had been reticent to share such information. Recognizing the importance of the access issue, FIAF itself created a specialist commission on the topic and went so far as to devote a special issue to this topic, a professional manual for access in its *Journal of Film Preservation*.^[13] Another significant benchmark has been the shift of emphasis in the types of films and media objects to be collected, preserved, and accessed.

The vast majority of public spending on archives in the "buccaneer" years and the early modern era was applied to laboratory costs associated with film-to-film duplication of classical Hollywood feature narratives. And although the movement toward film preservation had picked up considerable steam during these years, the level of federal funding continually decreased. In 1980, the highest annual disbursement (federal support for preservation through the NEA/AFI grants) was \$514,215 (for a fuller account of the AFI's early contributions to film preservation, see Mann).^[14] By 1992, the total Federal funding had declined to \$355,600 which allowed for the preservation of only 26 feature titles. In part, precisely because the AFI/NCFVP had failed in its mission to stop the erosion of Federal support and secure meaningful new sources of funding, to raise sufficient funds for film and television preservation, the field turned to a new organizational model, and embarked on a series of initiatives; including a much expanded commitment to film preservation on the part of the Library of Congress, the creation of the National Film Registry, and most significantly, the creation of a new, Congressionally funded entity, the National Film Preservation Foundation (NFPF) devoted solely to funding preservation and access projects among archives. Since 1997, the field has looked to the NFPF for financial support and cultural leadership.

This shift was accompanied by a broad reconceptualization of the idea of film preservation, influenced by the reformulation of technical standards for the long-term

survival of legacy collections. Thus the realization that optimal storage conditions were as important to preservation as film-to-film transfers leads to the epochal conclusion that nitrate, for example, could indeed wait.

More importantly, the public-sector archives began to focus on the importance of nonclassical titles by validating orphan films, a category of media types that includes amateur productions, nonfiction films (particularly news reels), titles in the public domain, and works whose copyright status was unclear or unprotected by large corporate interests. Proponents of orphan film studies cite their value as complex historical and cultural artifacts. It is also true that their unclear or ambiguous legal status affords archives additional flexibility in their handling and use. Indications of this new focus are plentiful: the establishment of the European Association Inedits (which now includes 41 archives as members), the ongoing research presented at the annual *Orphans of the Storm* conference, the amateur cinema topic for FIAF's 1997 Congress in Cartagena, and the many *Home Movie Days* that have been organized throughout the United States. Whereas the AFI used to channel federal funding to large U.S. archives for the preservation of nitrate-era feature films, the NFPF's funding priorities now clearly express this change in emphasis. As outlined on its Web site and in its annual reports:

The NFPF offers several types of grants to help public and non-profit institutions preserve and provide access to American orphan films. The grants are made possible through the National Preservation Act of 2005, the support of the Library of Congress, and the contributions of public spirited donors.^[15]

The generally anti-classicist orientation leads the NFPF to also include avant-garde works in the category of the orphan film. Indeed, one of its funding programs directly supports the preservation and archival treatment of avant-garde productions (the Avant-Garde Masters Grants). While the particularly social orientation of the orphan film movement validates local identities and cultural diversity, it also shares some of the theoretical tenets of New Historicism. The keynote address for FIAF's 1997 Congress, for

example, was delivered by Patricia Zimmerman, whose seminal *Reel Families* argues for the value of such voices in the construction of historical accounts that are alternative to traditional, grand narratives.^[16] Orphan works make for *new sources* of history. Arguably, one century later, Matuszewski might feel an appropriate measure of vindication.

France: Archives, Museums, and Libraries

Martine Poulain

Department of Libraries and Documentation, National Institute for the History of Art (INHA), Paris, France

Abstract

There are many similarities in the history and the evolution of contemporary French archives, museums, and libraries. All three have their roots in the Ancien Régime, but it was the Revolution that imposed their administrative structure. Over the centuries, all three have evoked similar questions and have been the subject of identical political and intellectual debates. At the end of the twentieth and the beginning of the twenty-first century, all three have finally become the object of ambitious public policies. Last, all three are today confronted with profound transformations—often experienced at a dizzying pace of change.

INTRODUCTION

In geographical area, France is the largest country in the European Union (EU) and the second largest in Europe. It has an extensive coastline, bordered on the north and west by the Atlantic Ocean and on the south by the Mediterranean Sea. The Alps, the Pyrenees, and the Rhine also provide natural boundaries. With an estimated population of 62,150,775 (July 2008) France is the second largest country in the EU. Governed under the constitution of the Fifth Republic, adopted in 1958, France has long time been a highly centralized state that has gradually ceded greater autonomy to local and regional authorities.

France not only has a long history of developing rich library and museum collections, it has been a leader in the field of archival training. The idea of the citizens' right to access archives dates from the French Revolution, and the principal of creating a national museum open to the public also dates from this period.

Since the nineteenth century, the central government has a tradition of offering financial support to national and local cultural institutions such as libraries, museums, and historic sites. This has led to the continuous enrichment of cultural heritage institutions, and these institutions have in turn provided a stimulus for the growth of cultural tourism among French residents and visitors from abroad. Attracting 81.9 million foreign tourists in 2007, France was ranked as the most popular tourist destination in the world.

FRANCE—ARCHIVES, LIBRARIES, AND MUSEUMS

There are numerous similarities in the history and the evolution of archives, libraries, and museums. All three have their roots in the Ancien Régime, but it was the Revolution

that imposed their administrative structure. Over the centuries, all three have evoked similar questions and have been the subject of identical political and intellectual debates. At the end of the twentieth and the beginning of the twenty-first century, all three have finally become the object of ambitious public policies. Today these three “places of memory” are all confronted with profound changes: the growth of collections, the technological revolution, the increase in costs, and the effects of globalization. Another important transformation has been the increase in the number and type of users, and archives as well as museums and libraries now welcome a much broader segment of the public. At the same time profound changes in professional philosophy have had a significant impact on the way in which resources and services of archives, libraries, and museums are conceptualized and how these three institutions are situated within the public space (Fig. 1).

ARCHIVES

According to the law on French archives (January 3, 1979), archives are defined as “the totality (ensemble) of documents, whatever their date, their form, or their format, produced or received by any person or corporate body, and by any agency or organism, public or private, in the course of their activity” (Article 1). This new definition is considerably broader than the one which prevailed in the past, and the current law is meant to give archives responsibility for conserving and making available the “memory of the nation.”

From the Ancien Regime to the Present

The well-known *Encyclopédie* of Diderot et d'Alembert described archives as “deeds or charters that contain the rights, claims, privileges, and prerogatives of a household,

Fig. 1 Map of France.

Source: CIA *The World Factbook*, <https://www.cia.gov/library/publications/the-world-factbook/geos/fr.html>

a city, or a kingdom.” Until the twelfth century, sovereigns traveled with the collection of documents which proved their legitimacy. However, the theft of this “treasure” during a battle lead Philippe Auguste (1165–1223) to organize his archival documents and to make plans for their conservation in a fixed location. The succeeding kings continued and augmented this organization of royal and governmental records. Over time, the archives increased to the point that in 1774 France had 5700 archival depositories. During this time specific disciplines were constituted such as paleography, which is the science of deciphering ancient writing through expert knowledge of the inks used as well as the writing material (such as parchment, vellum, or paper). Paleographical skills that were initially developed in monasteries became essential competencies of the first archivists.

One of the foundational acts of the French Revolution was the creation of the National Archives (September 7, 1790) as “the depository of all the acts which form the constitution of the kingdom, its public law and its administrative division into *départements*.” Throughout France the confiscation of the archives of the nobility lead to the establishment of bureaus for triage that were set up to process this historic influx of nearly a billion documents. The necessity of organizing the archives of the young republic lead to passage in June 1794 of a new law that established the right of citizens to have free access to the archives—a dramatic departure from the practices during the *Ancien Régime* when secrecy had been the rule. The *départemental* archives were created in 1796.

Nonetheless, during this period there were new concerns regarding the preservation of the national memory. Because the policies of the First Republic were diametrically opposed to those of the *Ancien Régime*, vandalism and destruction went with the establishment of new memory institutions: nearly two-thirds of the documents were eliminated, in most cases because they bore witness to the property and privileges of the hated nobility and clergy who produced them.

The archival institutions and practices established during the First Republic continued to be pursued during the nineteenth century even though France again became a monarchy. Archival knowledge continued to develop and new institutions were set up. The *Ecole des Chartes*, which still trains archivists, was created in 1821. In addition, the Daunou classification, an alphanumeric archival classification scheme, was developed; it is still in use today, although with modification. Despite advances in the field, by 1870 there were only 31 archivists at the National Archives. These archivists came under the authority of the Ministry of Public Instruction, and in 1897 the creation of a Directorate for Archives within the ministry underlined the importance of archives in regard to public policy. At the same time regulations were established regarding access to the archives and the appraisal and de-selection of documents.

After 1945 public investment in archives was strengthened, but, as often is the case in France, this lagged behind the enormous growth in the number of documents that needed to be collected and preserved, and did not keep pace with the increased demands placed by the public. In 1959, the Directorate for the Archives became a part of the brand new Ministry of Culture headed by André Malraux.

Situated in the heart of Paris in a historic mansion, the National Archives has for a long time lacked adequate space to process, preserve, and make its collections available. For those documents created after 1945 a new facility was inaugurated in 1969 at Fontainebleau (in the Parisian region), but this building soon became inadequate. In 1988 at the Paris site a new building was made available to users. Finally in 2004, the complaints of historians and researchers and the continuous petitions of archivists resulted in a project of much greater scope: the construction of an archival campus (*Cité des Archives*) in the Paris suburbs. Designed by the architect Massimiliano Fuksas and scheduled to open in 2011, this building will have a 60,000 m² surface, and a stocking capacity of 320 linear kilometers.

Contemporary Structure of the French Archives

The Directorate for Archives within the Ministry of Culture has an advisory role in regard to the public archives of France as well as regulatory functions and the responsibility for encouraging good practice. In addition, the directorate is charged with the evaluation, control and appraisal of classification, description, and conservation of the

archives as well as the provision of access to researchers and to citizens. The Directorate not only oversees the national archives, but also supervises the local, municipal, and *départemental* archives. In addition it supports the general development of archival science.

Created in 1988, the Superior Archives Council (Conseil supérieur des archives) is a consultative body for public and private archives and is concerned with both content and policy. The mandate of the Conseil supérieur is to analyze the situation and make recommendations but it has no administrative power.

The National Archives are responsible for the collection, conservation, and access to the administrative archives of the central government and its institutions. The ministries, public institutions, and all government agencies are required to deposit their archives in the National Archives which then processes them and makes them available. Only the Ministry of Defense and the Ministry of Foreign Affairs, for longstanding reasons of security, administer their own archives. Today the National Archives includes:

- The Historic Center of the National Archives (le Centre historique des archives nationales—CHAN) preserves and makes available archives covering the period from the Middle Ages to 1958; this collection occupies 100 linear kilometers of stacks.
- The Center for Contemporary Archives (le Centre des archives contemporaines—CAC) holds documents for the period from 1958 to the present day; it occupies 193 linear kilometers of archives.
- The Center for Overseas Archives (le Centre des archives d'outre-mer—CAOM) maintains the archives of the former “French Empire” with its colonies and overseas territories.
- The Center for Labor Archives (le Centre des archives du monde du travail—CAMT), is located in Roubaix, in the North of France. Opened in 1993, it is dedicated to preserving the papers of commercial enterprises and their workers. This new center provides evidence of the recognition by the government of a broadened contemporary conception of archives.

The collection, conservation, and access to archives is also carried out on at the level of the commune, the department, and the region. Local authorities in France include: 36,600 communes, 100 *départements*, and 26 regions. The regional archives have grown in importance along with the increasing power of the 26 regional administrative districts which were created in 1972 as political and administrative entities. The regional archives have also been enriched by the decentralization of the services of the central government.

The *départemental* archives collect the records of the 100 French administrative units known as *departments*. The importance of these collections has also increased as a result of the laws passed between 1983 and 1986; this legislation lead to the decentralization of public

responsibilities and strengthened the powers of the General Councils (Conseils généraux) that administer the *départements*. The *départemental* archives also administer the archives of small communes (fewer than 2000 inhabitants) that lack the resources necessary to maintain their own archives. The archives of the larger communes collect and maintain the records of the cities and towns. All of these local archives constitute a rich source of information on a wide range of subjects.

The law of June 20, 1992 enlarged the National Audiovisual Institute (Institut national de l'audiovisuel) legal deposit rights to all radio and television programming. As of 2008 these depository rights extended to most of the national television channels and to 17 public and private radio stations. This archives contains approximately 90% of all radio programs and 60% of all television programs created in France since the origins of radio and TV programming. By 2008, over 4,000,000 hr of programs could be consulted, and each year nearly 540,000 hr of radio and television programs are recorded. Nonetheless the French audiovisual archives prior to 1990 are vulnerable, because the recordings themselves (reel-to-reel tapes and cassettes) are threatened by physical deterioration due to chemical mutations over time. The disappearance of equipment needed to play these recordings also creates a threat to future access to these collections. If nothing were to be done, 835,000 hr of audiovisual archives would be lost between now and 2015 (almost one-third of the total). The preservation and the restoration of the original recordings and systematic digitization of these materials are both necessary. By the end of the twentieth century, when audio recordings and videos had expanded into the world of the Internet, the National Audiovisual Institute became interested in methods for the conservation of such materials originating from the Web.

Contested Issues Concerning Access to Archives

The concerns for the conservation of archival collections and the protection of the confidentiality of individuals had for a long time been considered more important than access, and this was particularly true for contemporary archives. Without special authorization, no access was allowed to documents issued after 1940 (a particularly sensitive period). As a result of the law of 1979, the regulations became more flexible. The period of restricted access was reduced, and is as follows:

- 30 years after being issued all administrative archives of a general nature can be consulted, with a possibility of exemption.
- 60 years restriction is placed on any document containing information on the private life of individuals, the security of the state, or national defense.
- 100 years for any archive concerning documents relating to judicial affairs or pardons.

- 120 years after the birth of the individual concerned for documents regarding personnel records of administrative employees and professionals.

Exceptions to these rules are allowed for by the law, and they are often accorded. This liberalization represented a real breath of fresh air and has permitted considerable progress in regard to the consultation of contemporary archives and the scholarly study thus made possible.

It was the progressive opening up of the archives that made possible significant advances in the study of topics relating to the Second World War and this in turn encouraged a modification of the collective memory and a change in our understanding of this dark period of French history. Greater access to primary sources has allowed progress in the study of the French state of Philippe Pétain, as well as the collaboration and the resistance, and it has enabled scholars to revisit issues raised by earlier historians (such as Robert Paxton, an eminent example of a historian who was not allowed access to the many of these archives when he worked on his seminal book, *Vichy France, 1940–1944. Old Guard and New Order*, 1971).

Nonetheless other primary sources remain inaccessible, such as archives related to the war in Algeria. It took the concerted activism of historians before the Prime Minister finally issued two circulars, the first in 1997 and the second 2001 that increased access to the archives of the Nazi occupation and those of the last colonial war. Then in 2001 the law on the information society established the right of each citizen to have access to all archives that personally concerned him or her. The potential for historical study of the World War II period was also increased by the belated return, beginning in 1994, of many kilometers of French archives (mainly governmental administrative records), seized by the Nazis in the early years of the Occupation. At the end of the war when the Nazis were defeated by the Soviets, these French documents were confiscated by the Russians who considered the archives to be legitimate spoils of war. The repatriated French archives consist of 1.2 million archival folders. However, not all these “special archives” have yet been returned, and their processing is an immense task.

Despite the increasing availability of archival materials, many researchers continue to protest against restrictions to access, and consider “the secrets of the archives” as not being in conformity with the exigencies of scholarly research and democratic process.

Private archives

An important aspect of the nation’s history and collective memory is not found in the various administrative archives described above. However, numerous initiatives have addressed a growing preoccupation with other sources of archives that can contribute to the

national memory and identity. Out of a desire to encourage the deposit of private collections in public archives, the Directorate of Archives of France has been systematically inventorying the private papers held by the National Archives and the départemental archives. This information has been entered into the Database for Orientation and Research in the Archives (Base d’Orientation et de Recherche dans les Archives—BORA). When completed, it will be possible for scholars to locate several 1000 collections of private papers relevant to their research.

In 1993, when the Centre des archives du monde du travail was opened in the north of France, the region was experiencing significant social and economic problems due to the changes in industrial production. Nonetheless, the new center for labor archives was also one of the signs of the commitment of public institutions to create a space for alternate memories. Located in a building that had been constructed as a factory in the second half of the nineteenth century, this facility collects the archives of industrial enterprises, commercial firms, professional bodies, unions, employers, associations, and even the personal archives of individuals who had played an important role in the professional world. These archives are largely made up of collections of private organisms that have no legal obligation to deposit their papers.

There are also a very large number of private archives in French libraries which often welcome the archives of local leaders, historians, artists, writers, etc. It is at the Bibliothèque Nationale on the rue Richelieu, within the Department of Manuscripts, that the largest number of private papers are conserved; these include not only the papers of writers but also scholars and statesmen.

The concern for preserving the diverse facets of national heritage has increased. Created in 1988 at the initiative of scholars and professionals from the publishing world, the Institute for the History of Contemporary Publishing (l’Institut Mémoires de l’édition contemporaine—IMEC) brings together, organizes, and preserves archival materials and research related to major publishing houses and important periodicals. L’Institut Mémoires de l’édition contemporaine also holds the papers of editors, writers, artists, researchers, critics, graphic designers, booksellers, printers, periodical editors, literary agents, journalists, and acquisition editors.

In a completely different domain, Génériques, an association created in 1987, has for 10 years taken on the task of inventorying the resources of public archives concerning foreigners in France. In addition, Génériques is working to safeguard and preserve private archives (associations, unions, and activists) related to immigration. Its goal is to make these papers available to the public in the hope of encouraging historical studies of immigration as well as increasing public awareness of the contributions made by immigrant populations throughout the history of France.

Transformations

Contemporary changes affect not only professional practice but also the formats that must be preserved and the nature of the public who use services of the archives. The advent of documents “born digital” (*tout électronique*) also represents a major change. Basing their work on the international standards for the description of documents (General International Standard Archival Description—ISAD-G), archivists find that more and more they are describing documents that utilize the XML format. French archivists also use Encoded Archival Description Document Type Definition (EAD DTD), which can be applied to the description of both paper and electronic documents. These standards and formats have been adopted because they permit the precise description of documents and allow for the exchange of records as well as database searching. Archives are also confronted with the long-term conservation of electronic documents. In numerous countries there are rules stating that under certain conditions the same legal validity is accorded to the electronic text as to documents on paper. However, as the French specialist, Catherine Dhérent asserts:

To describe digital texts, evaluate, and select them takes much more time than to organize archives in traditional formats or to prepare a finding aid like those used in the past—even one that is very detailed. . . The archivist must intervene much earlier in the life cycle of information.

In fact the initial structure of information is of primary importance, and from the time when electronic data is created, the intent to preserve these records must be factored into the software and the databases. Efforts to ensure effective records management and archival deposit must be integrated in all practices of those institutions concerned with preserving electronic records.

Archival services, like libraries, are also faced with the need to preserve Web sites, especially those of administrative authorities. Competencies expected of archivists now include application of new techniques for the capture of electronic data and the establishment of metadata, as well as knowing how to preserve digital documents. More than ever the archivists must plan in advance for tasks not made explicit and they must therefore become immersed in the professional or administrative milieu whose records they preserve and maintain. Archivists are no longer actors whose role begins after a document is written, but instead they must intervene early, anticipating the production of electronic texts in order to preserve them.

The public using archives has grown and diversified considerably during the last 30 years. In 1999, more than 300,000 individuals used the *départemental* and communal archives. Even though scholars and researchers are still numerous, the archives are now used by more and more people interested in genealogy who are researching their

family history. One-third of the users of *départemental* and communal archives are academics or administrators and one-third are retirees; the remainder include university students and individuals from other professions. Half of the users are undertaking genealogical research. General history or local history is the central interest of the majority of these readers. Half of them consult documents from the nineteenth century, and half use earlier materials, from the Revolution or the *Ancien régime*—notably parish records or registers of civil records.

Issues relating to the maintenance and preservation of archives is now of concern to a significant number of persons interested in social history or engaged in researching their family roots. The increasing presence of amateur genealogists has lead the archives of France to collaborate with the French Genealogical Federation in order to establish the portal Nomina. Set up in 2005, Nomina offers simple direct access to a significant collection of references and resources that can aid genealogists. Through this portal one can search four databases of names; within 3 years these databases included 13 million names, and the number is rapidly growing.

New segments of society also seek to be represented in the archives. At the same time research topics have diversified and multiplied and as a result more varied kinds of archival documents are being consulted. For example, because of an increasing research interest in daily life, ordinary social practices are now an integral part of the field of investigation. As the interest in historical sources are accompanied by the explosion of digital texts, paper, and pixels combine to increase in a dramatic way the reach of memory institutions that are now part of global information society.

MUSEUMS

Since the 1980s, French museums have experienced enormous transformations such as: a significant increase in the number of museums; construction of new buildings and ambitious renovations; a large growth in the number of visitors; an increase of large ambitious temporary exhibitions; and greater administrative challenges for managers. Trends include the temptation to commercialize museum practices; the redoubled efforts to attract philanthropy; and projects to “delocalize” certain important museum with branches elsewhere in France or abroad.

From Princely Collections to Public Collections

French princes and nobles have always collected works of art as signs of their power and their refinement. By the seventeenth century, the taste for collecting spread to other collectors (labeled “curieux”) whom Jean de La Bruyère, a satirical writer, mocked for their desire to simply amass an exhaustive collection. However, the

“cabinets of curiosities” bore witness to the growing knowledge in the area of natural history. An interest in antiquities developed as well as greater attention to historical monuments. Scholars such as Pereisc, Caylus, Gaignères, or Montfaucon established the concept of cultural heritage (*patrimoine*), and certain collectors opened their galleries to other amateurs. It is thought that the first museum was opened in 1694 in Besançon thanks to the donation of a priest who willed his books and works of art to the city on the condition that his collection would be open for consultation two times per week.

Starting in 1748, the Royal Academy of Painting organized a Salon with the aim of exhibiting and promoting the painters recognized by the king; at this time historical paintings were especially favored. From 1750 onward 100 paintings from the royal collections were presented at the Luxembourg Palace, which could therefore be considered the first example of a public museum. Soon a growing number of agents became involved in shaping aesthetic taste in France and bringing new perspectives to the art world; these individuals included the artists themselves, art dealers, new kinds of collectors, and the first art critics.

At the same time the field of museology was invented and attention was given to questions relating to the selection of works, the kind of space best adapted for the exhibition of the collection, and reflections on how to classify and organize works of art. During the 1770s several provincial cities opened museums, but these were generally scientific and technical. At the same time “lycées” dedicated to works of art were established; these institutions were often as a result of the efforts of scholars, artists, and writers. In addition, there were schools for design set up to train apprentice artists.

Although buildings and works of art that symbolized the hated Ancien Régime were sometimes destroyed during the French Revolution, it was also the Revolution that established and organized cultural heritage institutions dedicated to the arts. In addition, the Revolution encouraged the creation of three types of museums: the fine arts museum, the natural history museum, and the local museum. The newly established republic scrupulously inventoried “paintings, drawings, and statues,” “models and machines” and collections of natural history that were designated to become part of the Central Museum of the arts established at the Louvre in 1793. According to historian Dominique Poulot, this project was envisioned as a “world museum” (*musée-monde*). The intent was to return to the nation its treasures, reinterpreting them in the light of the new ideology of emancipation. These collections were enriched with art works brought back during the conquests of the Republic and later augmented by Napoleon I. The task of organizing these extensive collections fell to Dominique Vivant-Denon, one of the first directors of the Louvre. Similar pedagogical goals were envisioned for the Museum of Monuments, founded by

Alexandre Lenoir who sought to illustrate the history of French architecture.

During the nineteenth century, the paintings exhibited at the Salon des artistes français which were selected by designated members of the Academy of Beaux-Arts became more and more numerous, going from 1900 in 1848 to 7000 in 1880. Over time, the criteria of the Academy were contested and a group of artists created an alternative venue called the “Salon des refusés” (also known as the Salon of the independents) where the works of the impressionists were welcomed. The setting of aesthetic standards and of artistic achievement escaped from the control of the state and the growth of salons was the prelude to an increase in other types of exhibitions.

At the same time, museums spread throughout France and their interests began to diversify. The idea of national heritage (*la mémoire nationale*) began to be defined through museums. The same trend was seen in local history (*la mémoire locale*): regionalism encouraged the flaunting of specific local identities, sometimes contesting the dominance of an identity restricted to characteristics considered national. At the end of the century the Third Republic (1870–1940) established a policy of public funding that enriched provincial museums through purchases by the central government. The construction of museums in large cities was integrated into urban public works projects, and thus the discourse of local identity was translated into stone. Situated in the center of the city the museum often shared the same building with the municipal library, and it was never far from city hall.

During the last decades of the nineteenth century museography progressed as a discipline. However, despite the construction of some new buildings, museums and their treasures became mausoleums without adequate financial support (much like the situation of libraries during the same period). The image of the French museum was dusty and conventional, without impact on the contemporary world of art. The irruption of modernity thus took the path of subverting or bypassing existing institutions. Thus, in France until very recently museums lacked an openness to contemporary art and they failed to respond to important cultural and aesthetic trends such as the regional or local aspects of nineteenth century culture or the focus on popular culture, heightened in the twentieth century by the emerging disciplines of anthropology and ethnography.

The first part of the twentieth century was difficult for museums. Museum curators found their selection of works contested by the avant-garde, while at the same time they were confronted with the growing financial power of private collectors, art dealers, and galleries and soon became marginalized in the art market. Allotted insufficient funds by administrative authorities, French museums became somewhat fossilized around collections that were not being renewed.

Nonetheless, during the 1930s a new kind of museology and new preoccupations came to the fore. These included the contribution of the ethnographic perspective to the understanding of non-Western civilizations as well as a growing interest in popular culture in France. Such trends lead to the creation of different types of museums, such as the renowned Anthropology museum (Musée de l'homme) and the Museum of Popular Arts and Traditions, whose respective founders, Jean Rivet and Georges-Henri Rivière, were guided by the modern museographical ideas.

Museology was also evolving, and the accumulation of collections gave way to greater selectivity, accompanied by more effective exhibition techniques and a pedagogical discourse which was intended to aid visitors who were no longer left on their own to confront works of art unaware of the context of their creation. Henri Focillon, a scholar and director of the museum of Lyon, laid the foundation for the International Council of Museums, created in 1946 at a time when the museum world was becoming interested in international exchanges with the goal of creating standards for museum practices.

As was the case in the domain of archives and libraries, public policy initiatives in the museum domain were redoubled after the Liberation. A 1945 law whose aim was to increase the administrative support of the central government distinguished three types of museums throughout the country; this typology was based on the size and value of the collections. The largest were given the status of national museums, followed by those designated as classified museums (*musées classés*) and finally by smaller museums that were inspected from time to time by representatives of the central government. The idea of monitoring museums should not be thought of as retrograde Jacobinism. On the contrary, at this time, it represented greater governmental support for museum development and stimulated the professionalization of museum practice.

André Malraux, writer and author of the *Imaginary Museum* (*Museum Without Walls* in the English translation) was well qualified to become the first Minister of Cultural Affairs in 1959. Basing his policies on a desire to promote an aesthetic shock (*choc esthétique*) in the confrontation between the public and the works of art, his goal was to “make accessible the great works of humanity, and especially of France, to the largest possible number of French people” (Law of 1959 founding the Ministry of Culture). Malraux not only initiated the renovation of museums, he also saw to the construction of cultural centers (*Maisons de la Culture*) in the heart of the larger cities. These centers were a kind of “space for the totality of culture” offering concerts, theatrical performances, debates, and sometimes they even included an “*artothèque*” lending art that could be displayed at home. The *artothèque* usually contained reproductions of paintings or works by young artists. Despite his best efforts, Malraux’s objective of consecrating 1% of the national

budget to the activities of the Ministry of Culture was not attained until 1981 when the Left gained power.

Museums Today

The law of January 4, 2002 renewed the statute for those museums that are administered by public authorities. This law designated 34 national museums, thus emphasizing their scope and importance; national institutions includes: the Chateau of Versailles, the Louvre, the Orsay Museum, the Rodin Museum, the Picasso Museum, and the Museum of Franco-American Cooperation at Blérancourt, etc. At the next level are 1173 “museums of France” which are administered by local authorities or by associations. These museums hold collections that are in part owned by the central government, but the museums themselves are now under the responsibility of local or regional authorities. The designation “museum of France” is defined by specific cultural and scientific criteria: these establishments must

conserve, restore, study, and enrich their collections; make their collections accessible to the general public; plan and implement educational activities with the goal of assuring to all equal access to culture; and contribute to research and to the advancement of knowledge and to its diffusion.

(article 2). A High Council for Museums (Haut Conseil des musées) brings together representatives from different kinds of museums.

The total number of museums in France today is between 5000 and 6000 institutions. Numerous museums are under the authority of ministries other than the Ministry of Culture; others are administered by territorial collectivities, by association or even by private individuals, such as collectors. The city of Paris also is responsible for numerous museums such as Carnavalet Museum of the History of Paris, the Museum of the Petit Palais, the Museum of the Art and History of Judaism, etc.

Within the Ministry of Culture the Directorate for the Museums of France provides funding for the 34 national museums over which it exercises a supervisory role. In addition, the Directorate has an overarching mission of orientation, programming, and coordinating museums throughout France. The Directorate also has the responsibility to:

- Monitor and provide technical and scientific advice to museums that are administered by municipalities, by départements or by associations.
- Implement the government’s policy of contribution to the enrichment of national public collections.
- Establish and promulgate rules for the protection and conservation of works of art.

- Set rules for loans, and authorize or deny permission for works of art to leave French soil.
- Support the training of museum professionals.

Public collections of art are governed by the rule of inalienability; no works can be sold unless they are first “declassified.” The evaluation of works to be declassified is carried out by museum advisors who belong to one of the 26 Regional Directorates of Cultural Affairs.

Other services that support and coordinate museums are also under the authority of the Directorate of the Museums of France. One of these is La Réunion des musées nationaux, an agency whose main mission is to acquire works of art to enrich the national collections; the Réunion also organizes major exhibits and edits their catalogs as well as selling any tie-in products. Another body known as Center for Museum Research and Conservation in France (le Centre de recherche et de restauration des musées de France) carries out research in the domain of restoration and conservation and participates in the implementation of new practices and techniques.

As in other cultural domains, the last 20 years were marked by growing power of territorial collectivities. By 2008, half of the museum professionals were employed by regional or local museums. In order to structure and coordinate their activities, the départements often employ a museum advisor (*conseiller patrimoine*) who attempts to promote networking. The fine arts museums of Northern France and of Pas-de-Calais coordinate their exhibition programs and their public relations work. In Auvergne, an association to promote local museums has been established. In large cities, the Directorate of Cultural Affairs employs a museum advisor who supports the development of museums and seeks to establish partnerships with other institutions within the city, especially in activities that relate to public relations and education.

Local museums in France are not limited to fine arts, even though here the tradition of local history museums is less developed than that in Great Britain or the United States. Numerous French museums are dedicated to history, prehistory, ancient archaeology, natural sciences, while other focus on specific social or economic activities. Since the 1970s there has been a flowering of eco-museums as well as museums that collect objects related to popular culture, to professional, industrial or technological activities; in addition there are museums that collect artifacts representing the ethnographic heritage of France. There are over 200 of these kinds of museums throughout France—a fact which demonstrated the viability of a new socioeconomic orientation for museums.

Audacious Architecture

During the past 30 years there has been a spectacular development of museum buildings in France. Renowned

architects have been commissioned for numerous new building projects and for the audacious renovation of existing museums. The landscape has been radically transformed. This wave of construction began in 1977 with the Centre Georges Pompidou designed in an unabashedly modernist style by Renzo Piano and Richard Rogers. The building consists of eight levels that are entirely modular. All the weight bearing supports as well as the water pipes and ducts for electrical cables, elevators, and air conditioning were pushed out to the exterior of the building, thus giving the center a unique appearance that has been compared to an oil refinery by certain critics.

During the 1980s, numerous museums in Paris and the provinces have been renovated or rebuilt. In 1985, a private mansion in the Marais historic district on the right bank of the Seine was transformed into the Picasso Museum by the architect Roland Simounet. A year later three architects and interior designers working under the direction of Gae Aulenti carried out an even more radical transformation of the Orsay railway station in Paris, creating exhibition space for a museum consecrated to the nineteenth century.

In the late 1980s Ieoh Ming Pei, a renowned architect who is known for numerous projects, especially the new wing of the National Gallery in Washington, D.C., was chosen to renovate, modernize, and enlarge the Louvre. Pei's audacious design was centered around a stunning glass pyramid in the heart of the Louvre's courtyard. Another group of notable architects, J. M. Wilmotte, Rudy Ricciotti, and Mario Bellini, have been commissioned to carry out the interior design of the galleries of Louvre. This expansion was carried out from 1981 to 1999.

Jean Nouvel, architect of the Institute of the Arab World and the Cartier Foundation for Contemporary Art, constructed the Quai Branly Museum, dedicated to non-Western art; this innovative new museum opened in 2006. Numerous projects are now in the process of being constructed, such as a building in Paris by Frank Gehry which will house the private collection of François Pinault.

In the provinces, the construction of a new fine arts museum in Grenoble was followed by the Carré d'art (museum and library) in Nîmes designed by Norman Foster in 1993 and the Museum of modern art of Villeneuve d'Ascq. Important renovations were carried out in Lyon, Nantes, and Lille and many other cities. All these innovative constructions and renovations of French museums offer visitors the pleasure of viewing newly enhanced and enriched collections shown to their best advantage.

A Few Major Museums

The *Louvre Museum* occupies 160,106 m² of which 58,470 m² are used for exhibits. It is the third largest museum in the world after the Metropolitan Museum of Art in New York and the Hermitage Museum in Saint

Petersburg, Russia. In 1993, the Louvre became a public institution under the Ministry of Culture, and this change in its statute permitted the museum to enjoy greater autonomy. The collections of the Louvre cover the period from antiquity to 1848 and exhibits represent a wide geographical area from Europe to Iran, via Greece, Egypt, and the Near East. Among the most famous masterpieces are the Code of Hammurabi, the Venus de Milo, the Mona Lisa by Leonardo da Vinci, and Liberty Guiding the People by Eugène Delacroix. The renovation of the Louvre allowed for an increase of 30,000 m². The Pyramid of the Louvre is the center of gravity for the collections, and functions as the principal entry, allowing visitors access to the three wings of the Louvre palace: Richelieu, Sully, and Denon.

The *Orsay Museum* presents diverse works of the second half of the nineteenth century, from 1848 to the birth of Cubisme. By featuring artists born between 1820 and 1870, it provides the transition from the collections of the Louvre and the collection of the Museum of Modern Art at the Pompidou Center.

The *Pompidou Center* is the result of the vision of President Georges Pompidou (1911–1974) who wished to create an innovative cultural center in the heart of Paris—a center not only dedicated to fostering creativity in the plastic arts but also offering access to books, drawings and graphic design, music and cinema within the same building. The Pompidou Center houses an Institute for Contemporary Music, theaters for performing arts and movies, and the largest public library in Europe at the time—the Bibliothèque publique d'information (BPI). Occupying two levels of the Pompidou Center, the National Museum of Modern Art/Center for Industrial Creation holds 59,000 works, making it one of the most important collections of modern and contemporary art in the world (rivalled only by the New York Museum of Modern Art). Out of its vast collection, the Pompidou center offers 1330 works on permanent display, but it also has galleries for temporary exhibits as well as the Kandinsky library which offers a specialized collection of works related to twentieth century art. In the course of its three decades of existence, the Center has offered some remarkable exhibitions, such as *Paris–New York*, *Paris–Berlin*, *Paris–Moscow*, or later *Vienna, Turn of the Century* (1986).

The *City for Science and Industry* (*Cité des sciences et de l'industrie*), designed by architect Adrien Fainsilber, opened in 1986 and has since become very popular with the public. The mission of the Cité is to promote an understanding of science and technology to the general public, especially targeting children and adolescents. In addition, it attempts to stimulate the interest of citizens in the challenges to society that are linked to scientific and industrial research. Located in the immense La Villette Park, this complex offers many theaters and auditoriums, a music conservatory, and a concert hall.

In the course of the twentieth century non-Western art began to occupy a major place within museum collections.

This development was due in part to the efforts of artists known as Fauves and Cubists, as well as to the work of ethnographers such as Claude Lévi-Strauss and to writers and critics from Apollinaire to Malraux. The *Quai Branly museum*, opened in 2006, is entirely devoted to the arts of Africa, Asia, Oceania, and the Americas. Its goal is to stimulate the study of these objects using diverse perspectives, from ethnography to art history, and to recognize the importance of the civilizations and heritage of people sometimes marginalized by contemporary globalization of Western culture.

In 2007, a new national museum on the history of immigration (*la Cité nationale de l'histoire de l'immigration*) was opened. It is the goal of this new institution to collect, protect, interpret, and display artifacts relating to the history of immigration in France since the nineteenth century and to contribute to the development of new scholarly perspectives and to influence public attitudes (*mentalités*) by increasing the understanding of the role and contributions of immigrants in France. Narrative accounts, archival documents, photographs, drawings, and works of art are used to illustrate the history of immigrant experience. Among the important French historical museums one should also note those museums dedicated to the First or Second World War which have also benefited from recent building projects as well as new approaches to museology. Since 1988, more than 7 million people of all nationalities have visited the Peace Memorial dedicated to the Second World War in Caen, a city 73% destroyed during the summer of 1944.

The Museum Professions in Evolution

The curators of national or regional museums are trained at the National Heritage Institute (*l'Institut national du patrimoine*). Founded in 1990, the institute has as its mission the training of curators and conservators who work in cultural heritage institutions. These curators practice their profession in archives or museums; some conduct inventories and others work for organisms dealing with archaeology, historical monuments, or with other types of heritage collections in natural history, science or technology. Curators are appointed head of the national museums and major museums under local authorities; working under the curators are technical assistants (*attachés de conservation*) who belong to a national technical corps established in 1991. Trained in schools for territorial administrators, these technical assistants have become more and more numerous in museums operated by local authorities, and they direct some of the smaller local museums. Other staff in territorial museums include assistants and credentialed assistants with an expertise in conservation; both must pass a national examination. The guards are the most numerous museum employees, and they are given a double role of providing security and of welcoming the public.

The growth in the number of museums and the increase in temporary exhibitions has initiated or contributed to the professionalization of related occupations, such as registrars of works of art. It has also given rise to the function of exhibit planning, which is usually carried out by curators who are chosen either for their specialized subject knowledge or for their special competence in mounting temporary exhibits and organizing programs. Such exhibitions are often the moving force behind museums, attracting a different public than those who come to see the permanent collections. For major exhibits great care is taken as to the presentation, which is conceptualized by designers (*scénographes*). Finally, most museums now have a cultural service or an educational department which oversees a variety of interpretive activities offered to a diverse public of adults as well as children. These offerings include debates, meetings, concerts, lectures, or guided visits as well as pedagogical activities and special programs for schools.

For curators, scholarly expertise remains the primary requirement and they must be specialists in the art genre and period in which they work. Curators are increasingly engaged in research which primarily (but not solely), relates to catalogs focused on a single artist or accompanying a thematic exhibition. In addition to research and publication, the concern for documentation has lead museums to mount reproductions of their holdings online (<http://www.culture.gouv.fr/culture/bdd/bdd3g.htm>).

Opened in 2004, the National Institute for the History of Art (Institut national d'histoire de l'art—INHA) supports research in art history carried out by teacher-researchers in higher education institutions or by museum curators. To aid these researchers INHA has created databases, directories, dictionaries, and compilations of sources materials that are useful for research in art history. In addition, INHA has an important library with a rich collection of 1.7 million items that are used for specialized research in the history of art, archeology, and architecture. The institute also welcomes foreign researchers and contributes to the training of young researchers.

The School of the Louvre (Ecole du Louvre) is aimed at a broader public. Founded in 1882 and still located in the Louvre Palace, it offers courses in the history of art, archeology, epigraphy, history of civilization, and museology. It also welcomes individuals wishing to audit its courses, and offers evening courses and series of lectures for the general public.

The Growth of the Public

The great public success of museums and exhibits is not a recent phenomenon. The French Revolution inaugurated the doctrine that all citizens should share in the enjoyment of national treasures. From that time on a broad public has visited the Louvre and the Museum of French Monuments. It is estimated that number of museum visitors had tripled

by the end of the eighteenth century. The “grand tour” of Europe which became obligatory for wealthy families on the other side of the Atlantic also brought an increasing number of visitors to European museums, including some who came in search of their roots and their identity. At the same time growing crowds of French bourgeoisie were seen at the Salons: 360,000 persons at the Salon of 1870 and 500,000 at the Salon of 1874. Despite the burgeoning interest in art, the public who visited museums remained dominated by scholars or members of the elite and the nineteenth century did not greatly add to this audience.

Since the 1980s, the museum-going public has increased and diversified due to a combination of factors: the investments by public authorities in museums; the renovation of key museums; and the attraction of temporary exhibits not restricted by a narrow scholarly discourse and therefore open to a much wider audience. If the public was eager to respond to these new incentives, it was because the structure of the French population had changed during the intervening years. There were many factors that stimulated a much greater demand for cultural activities. These included: the general lengthening of schooling; the increase of the number of graduates from secondary schools and higher educational institutions among the middle class; an increased life expectancy; and the growth of cities. Nonetheless, only 30% of French citizens visit at least one museum per year.

The Louvre is the most visited museum in the world with 8.5 million visitors in 2008; that year the Pompidou center welcomed 5.5 million visitors, and Versailles 3 million—mostly foreigners as is the case at the Orsay Museum. Major exhibitions bring crowds of people ready to stand in long lines waiting to enter exhibit halls so packed that it is difficult to calmly reflect on or enjoy the works of art displayed. Examples include an exhibit of the works of Manet in 1983 that drew 700,000 visitors; another on Renoir in 1985 welcomed 825,000 visitors; 660,000 came to view the Gauguin exhibit in 1989; for Toulouse-Lautrec in 1992 attendance was 700,000, and for, Cézanne in 1995 630,000. Nonetheless, the large audience for exhibitions remains marked by social distinctions: museum visitors are still drawn from among the highly educated and from those in higher social and economic levels. Broad democratization of the museum-going public is still far from being realized.

In order to respond to large scale changes that require heavy expenditures in museums, France encourages philanthropy. This is done by offering a substantial reduction in income tax for corporations. If the work of art purchased is considered a “national treasure” and has been refused a certificate for exportation, the individual donor or the corporation can benefit from a tax reduction equivalent to 90% of the price paid for the work of art.

In 2007, the Louvre and the emirate of Abu Dhabi provoked considerable controversy. The Louvre assisted the emirate in planning a museum that would bear the

name of the Louvre for 30 years. French museums will organize traveling exhibitions and will loan works (300 initially, more subsequently). In return the emirate will deposit important sums of money [1 billion euros] into the account of a new International Agency for the Museums of France (Agence Internationale des Musées de France).

France, like a number of European countries, has not only developed a passion for heritage institutions and sites of memory (“*lieux de mémoire*”) but has also succumbed to the vogue of the “patrimonialisation du monde.” Everything represents heritage and every place is a site of memory in this movement that has led to both a greater openness and to a turning inward. If modernity and globalization extend one’s perspectives and stimulate curiosity, these trends also stimulate a desire to return to one’s roots, to be inscribed into a more circumscribed world, into a history and geography that are more familiar. Revealing an opening to the larger world, the celebration of heritage also bears witness to a certain fear of the future and a redoubled need to share common social beliefs and practices, a desire to belong to a community. Finally, as globalization has brought about mass cultural tourism, the great museums of France are welcoming an impressive number of foreign visitors.

LIBRARIES

Like museums, libraries have experienced unprecedented development at the end of the twentieth century. The provision of library resources and services has undergone a continuous reconceptualization and readjustment due to the transformation in educational and cultural policies, the evolution of professional practice, and the revolution in information technologies.

A Rich History

French libraries have had a very long, rich, and varied history. In the Middle Ages, monasteries were the major centers for the production of manuscripts, and their *scriptoria* were the source for many theological works. The monks were not only responsible for exegesis but also for the conservation and reproduction of manuscripts at a time when copying was the only means of reproducing and diffusing a work. Each manuscript was unique, because every copy could contain variants, glosses, and errors; it is this characteristic unicity that makes these manuscripts so valuable today. By the thirteenth century, the first universities and colleges established libraries where valuable large format, manuscript books were chained to lecterns. In contrast, the kings traveled with their books, and from 1483 onward the kings passed their collection intact from father to son. The royal library was first installed in a fixed location in the Chateau of Blois then moved to the Louvre

palace in the 1560s. Soon the first classification schemes and library catalogs were developed.

Meanwhile, the invention of printing and the era of religious disputes altered the world of books. Access to religious works in the vernacular was one of the challenges of the Protestant reformation, and around the same time scholars such as Erasmus of Rotterdam (1467–1534) and Michel de Montaigne (1533–1592) affirmed the right to personal reflection and free thought as an essential component of humanism. The library (“*librairie*”) of these humanists was a personally selected collection of works that became a space outside of the control of the authorities.

In 1521, François I made legal deposit of printed books obligatory—an act that has continuously enriched the royal library with books published in France. Nonetheless, the establishment of legal deposit was an act characterized by mixed motives; on the one hand, it reflected the king’s desire to collect and preserve all works published throughout the nation and, on the other hand, it represented his intent to control the printed word through the exercise of censorship. In addition to royal oversight there was also ecclesiastical control of French printing; the requirement that writings receive a license to be printed (*l’imprimatur*) from the Catholic church was one of the triumphs of the Counter-Reformation in face of the challenges by Protestant “heretics.”

Meanwhile educated princes, nobles, and other cultivated people began to collect personal libraries, and some of these were quite important. In the seventeenth century, Cardinal Mazarin (1602–1661) owned one of the largest collections of his time, enriched by the efforts of Gabriel Naudé (1600–1653), a librarian active in the Republic of Letters. By the time of the Enlightenment in the eighteenth century, books and libraries had become instruments for the conquest of public space, then opened to the exercise of reason, dialog, and freedom of thought. At this time libraries were more numerous, offered more abundant collections, and were sometimes opened to the public. Even the Royal Library was open to the curious (“*curieux*”) and to the amateurs two afternoons a week.

In France, the first establishment of libraries placed under public responsibility was an outcome of the emancipatory ideology and policy of the Revolution. These newly created libraries were supplied with books confiscated from the libraries of the aristocrats and the clergy, whose collections were sometimes expurgated. Between 4 and 7 million items were seized and placed in literary depositories (*dépôts littéraires*), then given to colleges; finally in 1803 they were entrusted to the communes. At this time the Royal library was renamed the Bibliothèque nationale (BN), and both the BN and a number of other large libraries were enriched by the works that were seized.

For a time this rich heritage was the glory of French libraries, and during the 1860s British librarians and

members of parliament who wished to develop libraries in their country, held up French libraries as the example to imitate. Although the municipal collections throughout France were slowly cataloged, preserved, and made available to the public, these libraries acquired few new works and their services to the public were limited. Paradoxically, the richness of the collections became a dead weight on municipal libraries; neglected by the authorities, these institutions only attracted scholars and students who appreciated their rare and precious works. However, by the end of the nineteenth century the demand for reading materials increased in France.

Literacy became much more widespread, and the working class as well as women and children were becoming readers. These changes lead to the creation of popular libraries (*bibliothèques populaires*) which were financed by philanthropic organizations, by cities, by schools, and by religious bodies. Although the collections of these lending libraries were often limited, they included carefully selected books, often chosen with the intent of using “good books” to combat the taste for “bad books”; the founders of these libraries also hoped that the working classes would engage in reading instead of pursuing leisure activities considered bad. Nonetheless, in addition to nonfiction works these libraries did loan out novels (a genre that was considered illegitimate for a long time). These popular libraries initially met with great success and it is estimated that there were tens of thousands of them by the late nineteenth century when they began to rapidly disappear.

In the early years of the twentieth century, modernist librarians struggled to gain acceptance of a new model of free public libraries inspired by examples they found in Great Britain and the United States. After the First World War, these reformers were able to point to model public libraries constructed by the American Committee for Devastated France (Comité américain pour les régions dévastées—CARD), a philanthropic organization active in the reconstruction of villages destroyed by the German invasion.

Jessie Carson, a librarian from the New York Public Library was responsible for the CARD library projects, and she oversaw the creation of five small libraries installed in wooden barracks. Although the CARD libraries were modest, they were nonetheless significant in the history of public librarianship in France. Later Carson worked with CARD and with French library leaders to establish a Paris public library branch that featured open shelves and used American cataloging and classification systems. Another American philanthropic organization later gave the Paris municipal library system the first children’s library with open shelves. Known as l’Heure joyeuse, this collection was directed for many years by Marguerite Gruny, who is considered a great pioneer of children’s services in France.

After the Second World War important new policies for library development were put in place. Within the

Ministry of Education a new Directorate for Libraries and for Public Library Services (*Direction des bibliothèques et de la lecture publique*) was established. At the départemental level the Directorate set up Central Lending Libraries (*Bibliothèques centrales de prêt-BCP*) in order to encourage the development of rural public library services in a country that still had a significant population living in rural areas. Charged with bringing the “food for the spirit” to homes in small communes and rural areas, these Central Lending Libraries deposited book boxes in schools and town halls, sent out bookmobiles that traversed the countryside, and later offered users direct access to the central facility whose shelves were filled with books.

The Directorate also promoted significant development of university libraries by assuring that they were allotted greatly increased financing, better facilities, and more staff. Significant investment in libraries and in the advancement of librarianship continued into the 1960s. This enabled the restructuring and strengthening of training for librarianship, and provided incentives for professional meetings and publications. In addition career opportunities in the field were improved, and the National Graduate Library School (Ecole nationale supérieure des bibliothèques) was established to train professionals at a level equivalent to a master’s degree.

Despite considerable progress in the field, it was not enough to keep up with new demands placed on libraries by the rising educational and cultural level of the population and the rapid growth of specialized knowledge which stimulated an exponential growth in publishing. During the 1970s, French libraries again experienced a crisis. Renewed efforts first came at the local level as cities finally decided to develop new cultural policies to meet the needs of urban populations who were more highly educated than in the past. The opening of the new municipal library in Lyon in 1972 and that of the *Bibliothèque publique d’information* at the Centre Pompidou in Paris in 1977 clearly demonstrated the huge popular success of rich open-access collections that were regularly updated. At the same time there were numerous new construction projects as well as renovations of buildings and renewal of collections. At the same time libraries began offering books and other materials in a variety of formats. A new term, “médiathèque” (media center), was chosen to signify the wide range of materials and formats offered by these facilities whose development found a favor among city policy makers.

At the national level after 1981 the left wing coalition government vigorously supported the development of public library services. The renaissance of university and research libraries came somewhat later, and it was not until the late 1980s that universities received an important increase in funds to develop their libraries.

Today, there are several types of library systems or networks in France.

- Municipal libraries under the authority of cities; they may benefit from support from the central government, especially in regard to construction.
- Départemental libraries, governed by départemental authorities; their mission is to promote the development of library services in cities with fewer than 10,000 inhabitants;
- School libraries which include centers for documentation and information (CDI) offered by most secondary schools and middle schools, and library documentation centers (bibliothèques centres documentaires—BCD) found in a certain number of primary schools;
- Academic libraries that belong to universities and are placed under the authority of the ministry in charge of higher education;
- Libraries under the authority of the Ministry of Culture and directly financed by the ministry. These include for instance the Bibliothèque nationale de France (placed under the ministry in 1981) and the BPI at the Centre Pompidou.

The Transformation of Public Libraries

The development of public libraries in France has occurred along several important lines, and could be thought of as the implementation of professional philosophies and practices which originated in the nineteenth century, first being used in the young American democracy and then spreading to northern Europe. These practices, adapted to twenty-first century France, include:

- Providing extensive multimedia collections regularly updated and enriched.
- Facilitating easy use of the collections by offering readers direct access to all the types of materials from books to electronic resources and DVDs.
- Fostering a welcoming ambiance and an openness to all levels of readers from experienced scholars to novice users.
- Offering nonjudgmental services to all users, whether their reading needs are cultural, educational, informational, or recreational.

The above principles of service have been widely adopted and to them have been added two more principles that may be specifically French. First is the importance given to architecture and also to the use of space in a way that not only promotes the shared national heritage but also links cultural needs with the common good. Second is the desire to respect the tastes of the readers and, at the same time, to promote cultural policies which are characterized by a refusal of librarians to follow the simple supply and demand logic of the market place.

In 2006, France had a total of 2913 municipal libraries which employed 24,200 staff members and occupied 1.8

million m² of shelf space. Their collections provide users with access to 100 million items: 90.5 million printed materials (2.6 books per inhabitant only); 8.4 million pieces of music or discs; nearly 1.4 million films, videos, and still photographs, as well as language learning materials and an ever increasing number of electronic resources and digital documents of all types. Annually, municipal libraries acquire 4.9 million printed works (or 18 printed works per 100 inhabitants), purchased at a cost of 2.72 Euros per capita, and about 800,000 CDs or DVDs. However, it is audiovisual materials and electronic resources that have increased most rapidly, both in terms of their importance as a proportion of the collections and in terms of items loaned. These collections are largely available through direct access, which has radically transformed the relationship between the users and the knowledge or information they need. Now people can make use of the library without preconceived ideas and without knowing exactly what they are looking for.

The 97 départemental libraries (Bibliothèques départementales de prêt, BDP, which were known as Bibliothèques Centales de prêt prior to 1992) offer services to the 30 million inhabitants of France who live in 17,000 communes with a population of less than 10,000. They offer a total of 27 million print and nonprint materials (90 works for 100 inhabitants) in 17,000 libraries or book deposit stations, buying a total of 1.5 million documents a year (1 Euro per inhabitant per year). The départemental libraries also assist small municipal libraries and intercommunal libraries with their programming and operations. In addition, they provide support for the smallest library units known as “*bibliothèques-relais*,” and they send rotating deposits of books to schools, daycare centers, town halls, or to prisons and retirement homes. In addition, they provide for bookmobiles (bibliobus or médiabus) that offer direct access to their collections and also provide training to volunteers who staff the small book depositories or libraries.

Now very well integrated into local educational and cultural policies, public libraries have increased their efforts to partner with other civic organizations; they participate in many kinds of cultural programs and activities, and they promote reading in disadvantaged neighborhoods through outreach programs. Public libraries also network with other educational and cultural institutions and organizations, such as schools and associations. In a number of cities, libraries work with diverse institutions and agencies to plan and coordinate city-read programs (*ville-lecture*).

One of the weaknesses of French administration is the extreme partition and dilution of political responsibilities among 36,700 communes, each of which has considerable autonomy within its jurisdiction. In contrast, other European countries started regrouping their smallest territorial divisions into larger units during the mid-1960s; for example in Great Britain there are only 209 local authorities. It seems that the time has finally come in France for

cooperation and sharing responsibilities through inter-communal groupings. For the past decade and a half at the départemental level elected officials have often worked together in developing joint cultural policies and programs, and they have frequently taken on responsibility for promoting reading through various federated efforts.

School, Academic, and Research Libraries

For a long time French academic and school libraries have suffered from the indifference of public policy makers, a fact which remains paradoxical in a country with a strong intellectual tradition. In the long sweep of history there are a number of reasons for this situation. Those countries that were predominantly Catholic had a longstanding tradition of clerical control over the written word, because the church wished to monitor reading and “protect” readers. In contrast, Protestant countries claimed the right of individuals to have direct access to the Bible which was read in the vernacular. Meanwhile, in France aristocratic traditions favored an individual relationship with reading, which depended more on the wealth of personal collections, often inherited, than on the public provision of libraries. These aristocratic traditions in regard to education and cultural questions (so well analyzed by Alexis de Tocqueville), still have traces remaining today in contemporary attitudes, especially among the elite. Finally, educational system in France for a long time favored orality and privileged the spoken words of the teacher (*maître*) to the written word. Educational authorities also devalued the practice of gaining knowledge based on everyday experience and not simply by reading literary texts.

These factors explain why, despite significant funding in the nineteenth century, school libraries have had to wait until the mid-1970s to be given professionally trained personnel. It was not until the 1980s that school libraries were present in a large majority of schools. Centers for documentation in schools nowadays are expected to play a double role: supporting the instructional curriculum and providing increased opportunities for students to gain access to the broader culture. The CDI in secondary schools and middle schools teach young people to make use of all kinds of printed and electronic resources, and they now think of themselves as having a dynamic role of key agents for the modernization of the relationship that students have with knowledge.

Within universities and research institutes, the modernization of library collections and services has passed through several stages. In the traditional French system, universities are largely financed by the central government and are almost free to students. This has been changing since 1985 when universities entered into a contractual relationship with the government. University finances still depend on the number of students served, the level of study offered, and the disciplines covered, but now their

funding is also based on a four-year plan and on the evaluation of performance. Regional authorities also contribute to the support of universities, especially in the area of construction. In July 2007, a law was passed giving greater autonomy to the university in its relationship to the government, and university administrators were given much broader responsibilities.

Under these new regulations, university libraries have become “shared services” that are expected to coordinate acquisitions and prepare union catalogs to provide federated access to all resources offered on the campus. As in the past, university libraries have to provide learning materials for a more and more massive student body (1.4 million students, or 55% of all those students who have completed secondary school and have successfully passed their baccalauréat examination). At the same time these academic libraries must furnish researchers with specialized resources that are becoming more and more numerous and more onerous to acquire. There has been considerable tension between these two missions—to provide for both the needs of beginning students and advanced researchers. In the 1980s, specialized centers were established for the acquisition and diffusion of scientific and technical information (*Centres d'acquisition et de diffusion de l'information scientifique et technique—CADIST*); through this coordinated program certain university libraries that already had rich collections in a particular domain of knowledge were given national responsibilities.

Another example of cooperation is the Couperin consortium of French research libraries. Set up in 1999 to negotiate favorable pricing for electronic periodicals, Couperin also coordinates strategic initiatives in regard to publication and dissemination of international scientific and technical publications in the context of globalization. Another very important collaborative effort involves the creation of a union catalog containing information on the holdings of more than 2000 participating libraries in France. Known as the university documentation system (*Système universitaire de documentation—SUDOC*), this database, which joined Worldcat in 2008, contains over 8 million records and offers location information for 25 million items; it also provides information on periodical collections in 4200 institutions. In 2008, over 25 million data bases searches were conducted using the SUDOC catalog. In addition SUDOC collects, archives, and offers access to French theses in electronic format and offers a portal providing access to a number of other digital resources.

Academic libraries in France have experienced an impressive increase in the number of users. In 2006, 62% of all university students were active users and visited the library more than 50 times per year; statistics show that the total number of visits had doubled since 1990. University libraries throughout the country were open 58 hr per week on average. A total of 69 million volumes of printed

works are available in all French university libraries (30 million books and 39 million of bounded volumes of periodical) and each year 1.4 million books are acquired (less than one volume per student). In addition, university libraries subscribe to 141,000 printed periodicals and 480,000 electronic periodicals. As elsewhere the impact of new technologies has been overwhelming and the increase in electronic resources has expanded exponentially; for example the number of subscriptions to electronic journals grew by 30% between 2004 and 2005. Although the expense per user for acquisitions varies, the average per capita acquisitions expense in French university libraries has increased fourfold since 1990 and in 2006 it had risen to 70 Euros. Training students to use library resources is strongly encouraged. In contrast to what has happened in other countries following the development of mass use of the Internet, in France the use of libraries is stable, although consultation of printed materials in the library has fallen slightly—by less than 4% (i.e., 13 items per person per year). Interlibrary loan has experienced a slight decline, and the provision of electronic documents is not yet sufficiently developed in France.

Modern Buildings and a Growing Public

A library tour in France offers fine examples of architecture including new construction and the renovation of historic buildings. If architectural achievement is shown through large projects (such as the wave of construction of municipal libraries with a regional vocation), smaller libraries also demonstrate the significance of the library in urban development policies as well as highlighting the talent of the architect. During the 1970s, the concept of the library as a temple or cathedral was rejected in favor of libraries integrated into fabric of the neighborhood, housed in newly constructed facilities that were intentionally modest. In contrast, the end of the twentieth century saw a triumphal return of the landmark library, with striking architecture that had a certain seductive power. Nonetheless this return to libraries that are monumental, or at least built on a grand scale, did not minimize questions concerning urban development or social issues. Sometimes it was decided that a new library building should be not situated in the city center, but should instead be located in an outlying suburb where it could give renewed life to a neighborhood that had a negative image. In such a location, the library could also serve to promote books among disadvantaged populations who were less likely to be readers. The construction of a library thus has become a major element of the cultural policy of cities and at the same time has become a factor in urban planning and social development.

Library space planning and interior design has not only been the object of considerable attention in France, but has also become the physical expression of the intellectual and

utopian ideology of the contemporary *médiathèque*—a concept which calls for unimpeded passage from children's spaces to adult reading areas and reflects a holistic approach to cultural activities, bringing together reading, listening to music, watching documentary or feature films, and consulting electronic materials in all forms and formats. The new ideal of the *médiathèque* also represents a dramatic shift in focus—from collection-centered structures and practices to a user-centered orientation. The emphasis is now on the intellectually curious reader, open to all kinds of resources and services, disposing of free time to browse the shelves, and sample their diverse materials—a kind of all encompassing reader (*lecteur total*). The intellectual itineraries and journeys of this new type of reader are now the focal point of the library, which offers its collections and services with the unique goal of facilitating, enhancing, and maximizing their use. Several principles have become central in every library design project; these include attention to the flow of movement through the library; openness in the arrangement of spaces for reading and consultation; and requirements for transversality and fluidity.

At the beginning of the twenty-first century, 43% of the population in France visited libraries and 21% were registered library users. The percentage of the population visiting a library has doubled between 1989 and 2005. Municipal libraries have experienced the greatest increase: 35% of the population visits the library and 20% are registered, with children accounting for 35% of registered users. The modernization of libraries has stimulated an increase in the number of new users and once open access to the shelves became common librarians observed a considerable increase in visits by individuals who are not registered borrowers, and whose presence had previously been quite marginal in terms of library statistics. The library, which had once been above all a place where one came and quickly selected books to borrow, has now become a place where more people remain for a longer time, profiting from the collections, enjoying the ambiance and the comfortable space, and appreciating an opportunity for sociability with few constraining rules. Nonetheless, despite the spectacular increase in the use of municipal libraries, the percentage of the public who visit libraries in France has remained considerably lower than that in the United States, Great Britain, or in Scandinavia where libraries serve 60% to 80% of the population.

Sociological studies have often emphasized socio-cultural differences at play in regard to the use of libraries and in the reading of books. For example, young people visit libraries more than their elders, but less than they did 20 years ago and those groups who are over represented among library users include the most educated segments of the population, upper level professionals, and the middle classes in general. Gender is also a factor and women library users are more numerous than men. Finally registered borrowers are not necessarily loyal library users;

only one-third of them renew their membership each year. Furthermore, the number of books borrowed by registered users has declined among adults, only 18 books were taken out per borrower per year in 2006,

La Bibliothèque nationale de France

Despite major nineteenth- and twentieth-century efforts to enlarge the facilities of the Bibliothèque nationale on the rue Richelieu, it lacked adequate space. As a result, the tension between conservation and access to the collections became more and more acute. Confronting considerably increased demands, the Bibliothèque nationale was forced to consider drastic measures. In 1988, President Mitterrand announced his decision to provide France with “one of the largest and most modern libraries in the world.” The design of the architect Dominique Perrault was selected. As in any profound change, the plans for a radically new library were plagued by early difficulties, including polemics as to how the project should be conceptualized, its location, and the conditions necessary for the conservation of the collections as well as how to provide access to the public.

Situated in the east of Paris with a surface of 207,000 m², the François-Mitterrand site of the BNF opened in 1998, offering two levels of complementary services and collections. The upper garden level, which is open to the general public, offers a seating capacity of 1700. Here one can consult a research collection in all areas of scholarship-science, the arts, history, literature, and law; the collection offers access to 300,000 works available on open shelves, 3,500 periodical subscriptions, 3,000 films, 10,000 musical recordings, a digital library, and numerous databases. Located on the lower garden level, the research library offers access to 10 million volumes of printed materials, 95,000 films, 900,000 sound recordings, and 60,000 multimedia materials. These vast collections have been acquired over many centuries through copyright deposit or as a result of gifts, collections bequeathed to the library, exchanges, and acquisitions by purchase. The reading rooms on the lower level offer seating for 1,900 users who have open access to 290,000 volumes and 4,000 periodicals as well as audiovisual and multimedia materials and electronic resources.

In addition to these new offerings are collections conserved in specialized départements located elsewhere in Paris. In the historic building on the rue Richelieu one can find:

- The Département for Prints and Photographs (15 million items acquired through copyright deposit).
- The Département of Occidental and Oriental Manuscripts (225,000 works including the collection of oriental manuscripts written in 100 languages on diverse writing materials, e.g., clay, papyrus, palm leaves, etc.).
- The Département of Maps and Plans (600,000 printed and manuscript maps 104 globes and 10,000 atlases).

- The Department of Coins and Medals and Antiquities, which originated in the collection of the kings of France, and now contains more than 530,000 items.
- The Department of Music which receives copyright deposit for printed music and also administers the Library and Museum of the Opera; the combined collections consist of 2 million items.
- The Department of Performing Arts has approximately 3 million items related to cinema as well as theater and opera. These collections will soon be renovated and opened for a wider consultation.

The BNF also administers Library of the Arsenal which has a rich collection of literary materials and works on the history of ideas from the sixteenth century to the nineteenth century (contains 1 million printed materials, 14,000 manuscripts). In addition the BN administers other units devoted to preservation and restoration.

Each year through copyright deposit the library adds 170,000 monographs, 34,000 pamphlets, 1.3 million issues of periodicals, numerous audiovisual materials and electronic resources, and nearly 40,000 specialized items. Items acquired through purchase include 60,000 volumes in foreign languages. The BNF has also been charged with responsibility for archiving the Web; this is carried out by Web crawlers programmed to automatically collect this data. However, to capture sites on the deep Web and to take into account frequent changes within each site, manually assisted procedures are needed.

The general catalog of the BNF maintains cataloging records for all kinds of media; in 2008 it contained 5 million authority records and over 10 million bibliographic records. In the course of its reorganization, the BNF has pursued important collaborative projects with other libraries in France that have rich cultural heritage collections and specialized research materials that complement those of the national library. These partnerships in specific focus areas include various kinds of cooperative efforts such as the retrospective conversion of catalogs, collective bibliographic databases and abstracts, joint conservation efforts, and collaborative digitization projects. One result of this kind of cooperation is the French union catalog (*le Catalogue collectif de France*) which includes descriptions of the collections of 4000 institutions and allows users to find the location of 15 million items.

Gallica, the French digital library project launched in 1997, offers access to 3,50,000 items, of which 90,000 digital works, more than 2,30,000 images, and many hours of audio recordings. This collection of images and printed works covers many disciplines such as history, literature, science, philosophy, law, economics, and political science. Although Gallica now contains mainly image files, in cooperation with the European Digital Library, it plans to make available searchable text files at a rate of 100,000 documents a year between 2008 and 2010.

Other digital projects involved cooperation between libraries and research institutes, governmental bodies, or scientific publishers. As the result of cooperative efforts of four publishing houses and the BNF the Cairn portal has been created to offer access in digital form to articles appearing since 2001 in 126 journals in humanities and social sciences. Another portal named Persée has been sponsored by the Ministry of Higher Education in order to provide access to other scholarly journals essential to the work of French researchers. Other important, large scale digitization projects are now underway in municipal libraries that contain important historical collections. Such initiatives are flourishing, and now many libraries find that their daily operations must include digitization of historic collections or preparation of electronic databases needed by the communities they serve.

CONCLUSION

The tidal wave brought by the Internet and the promise of digital collections has radically transformed the work of the libraries and archives, but also of museums, and it has also changed the practices and expectations of users. The entire documentary cycle (from the acquisition of materials to their use) has been radically transformed by this technological revolution that has modified how collections and constituted and processed, organized, and made available. In addition, it has profoundly transformed the nature of learning, the representation of knowledge and attitudes toward the written word.

Functional Requirements for Subject Authority Data (FRSAD): Conceptual Model

Marcia Lei Zeng

University of Ljubljana, Slovenia

Abstract

Functional Requirements for Subject Authority Data (FRSAD) is the third model of the FRBR family developed by IFLA. This paper traces the history of the development of the model through the activities of the Working Group that developed the model (Part I), and describes the constructs of the FRSAD model, including the entities, attributes, and relationships defined in the FRSAD model (Part II). The paper also summarizes a number of issues around the model (Part III) and discusses application-related studies (Part IV).

I. IFLA FRSAR WORKING GROUP AND ITS ACTIVITIES

Background

In 1998, the International Federation of Library Associations and Institutions (IFLA) published the Functional Requirements for Bibliographic Records (FRBR) conceptual model, which identified entities, attributes, and relationships based on a logical analysis of typical data included in bibliographic records. The FRBR model divides the identified entities into three groups:^[1]

1. Group 1 contains four entities that represent the different aspects of user interests in the products of intellectual or artistic endeavor. These are
 - a. *Work*—A distinct intellectual or artistic creation
 - b. *Expression*—An intellectual or artistic realization of a *work*
 - c. *Manifestation*—A physical embodiment of an *expression*
 - d. *Item*—A single exemplar of a *manifestation*
2. Group 2 contains entities defined as actors or those who are responsible for the intellectual or artistic content, the physical production and dissemination, or the custodianship of Group 1 entities. These are
 - a. *Person*
 - b. *Corporate body*
3. Group 3, as defined by FRBR in relation to Group 1 and 2, represents an additional set of entities that serve as subjects of intellectual or artistic endeavor *works*. They are
 - a. *Concept*
 - b. *Object*

c. *Event*

d. *Place*

Continuing the tradition set by the IFLA FRBR model, two new IFLA working groups (WG) were formed: the Working Group on the Functional Requirements for Numbering and Authority Records (FRANAR) and the Working Group on the Functional Requirements for Subject Authority Records (FRSAR).

FRANAR WG was established in 1999 to develop a conceptual model for authority records. The WG released a draft of the Functional Requirements for Authority Data (FRAD) model in 2007 and published the FRAD Final Report in 2009, parallel with the work of the FRSAR WG. The FRANAR WG defines authority records as aggregates of information regarding entities that are assigned as controlled access points in bibliographic records.^[2] Although all three FRBR entity groups (with the “Family” entity added to Group 2 by FRAD) are covered in the FRAD conceptual model, its major focus has been given to Group 1 and 2 entities.

The FRSAR WG was formed in April 2005 to report to the IFLA Classification and Indexing Section. The original terms of reference were

- Build a conceptual model of Group 3 entities within the FRBR framework as they relate to the aboutness of *works*
- Provide a clearly defined, structured frame of reference for relating the data that are recorded in subject authority records to the needs of the users of those records
- Assist in an assessment of the potential for international sharing and use of subject authority data both within the library sector and beyond

By definition, IFLA FRBR Group 3 entities “represent an additional set of entities that serve as the subjects of *works*. The group includes *concept* (an abstract notion or idea), *object* (a material thing), *event* (an action or occurrence), and *place* (a location)”^[3] (emphasis added). This part of the FRBR model has been questioned as to whether it is sufficient to cover everything that can be viewed as a “subject” of a *work*, for example, “time.”^[4,5] One of the FRSAR terms of reference, as listed above, was to build a conceptual model of Group 3 entities within the FRBR framework as they relate to the “aboutness” of *works*. In this framework, all controlled access points related to all three entity groups, as defined by the FRBR conceptual model, have the potential to be the topics of a *work*. In other words, Group 1, 2, and 3 entities can have an “is-the-subject-of” relationship with the *work* (to be discussed in detail in the following sections.)

The FRSAR Working Group

The FRSAR WG was chaired by Marcia Lei Zeng (who was at the time the Chair of IFLA’s Standing Committee of the Classification and Indexing Section) and cochaired by Maja Zumer (who was a member of the same Committee and also of the FRBR Review Group) and Athena Salaba (who also served as the secretary of the WG). In May 2005, an invitational workshop titled “FRBR in 21st Century Catalogues” was held in Dublin Ohio, hosted by OCLC. It was during this workshop that the FRSAR WG chairs started to invite WG members and Advisory Group (AG) members. Table 1 lists WG and AG members who served on this task and contributed to the development of the FRSAD conceptual model (Table 1). The WG divided tasks among members of two groups: the User Tasks Subgroup, led by Salaba and including members of Bultrini, Chan, Riesthuis, Miller, McGarry, and Zeng; and the Subject Entities Subgroup, led by Zumer and including members of Bultrini, Chan, Furner, O’Neill, Vizine-Goetz, and Zeng.

In addition to the whole group meetings held at IFLA Annual conferences, numerous meetings, combined with teleconference facility, were conducted from 2005 to 2009, not to mention many emails among the members. Kent State University, OCLC Headquarters (both located in Ohio, United States), and IFLA provided support or facilities for these meetings. The WG also conducted meetings in other related professional conferences, with the support of the hosting institutions, especially the University of Vienna, during the International Society for Knowledge Organization (ISKO) 2006 Conference, and the University of Montréal, during the ISKO 2008 Conference.

FRSAD Development Timeline

The WG started by defining user tasks as soon as the subgroups were formed. A survey on the use of subject authority data was conducted worldwide, and over 800

responses were received between June and August of 2006. At the June 2006 ISKO Conference in Vienna, the WG had a full-day meeting to discuss the conceptual model according to the first term of reference given to the WG by IFLA (i.e., to build a conceptual model of Group 3 entities within the FRBR framework as they relate to the aboutness of *works*). At that point questions around “Group 3” started to emerge. The WG meetings at the 2006 IFLA Conference in Durban, South Africa, resulted in a number of alternative models. Based on two tests conducted by the WG members, extensive discussions of existing conceptual models of aboutness and the alternative FRSAD models examined during 2007 and 2008, the WG had a major breakthrough. Eventually a conceptual model was developed and finalized at the ISKO conference in Montréal and the IFLA conference in Québec City, Canada, in August 2008. A draft report was completed at the end of 2008, and reviewed by the Advisory Group members. The revised Draft Report was officially released for its worldwide review in June 2009. It received many comments by individuals and institutions, which provided a solid foundation for the WG to revise and prepare the Final Report. The FRSAD conceptual model was presented at the 75th IFLA General Conference and Assembly held in Milan, Italy, in August 2009. The Final Report, titled “Functional Requirements for Subject Authority Data (FRSAD): A Conceptual Model,” was

submitted for approval in April 2010 and was approved by the IFLA Standing Committee of the Classification and Indexing Section in June of the same year. In July 2010, the Chair of Division III Library Services, on behalf of the IFLA Professional Committee, informed the WG that the FRSAD Final Report was validated and released for publication by IFLA. The FRSAD Final Report was published as the 43rd volume of the IFLA Series on Bibliographic Control by De Gruyter Saur in May 2011 (Fig. 1).

The FRSAD Final Report contains seven chapters and four appendices. Some sections in the Final Draft, such as the research-based background, the development processes, and implementation examples, were moved to the appendices in the Final Report. The final chapters and appendices are

- 1. Background
- 2. Purpose and Scope
- 3. Entities
- 4. Attributes
- 5. Relationships
- 6. User Tasks
- 7. Conclusion
- Appendix A. Modeling Aboutness
- Appendix B. Relationship of FRSAD with FRBR and FRAD
- Appendix C. FRSAD Model and Other Models
- Appendix D. Examples from Subject Authority Systems

FRSAR Working Group Studies

The FRSAR WG identified four user groups of subject authority data. They are: 1) information professionals who create and maintain subject authority data, including cataloguers and controlled vocabulary creators; 2) information professionals who create and maintain metadata; 3) reference services librarians and other information professionals who search for information as intermediaries; and 4) end-users who search for information to fulfill their information needs.^[6]

In an effort to define user tasks based on empirical data, the FRSAR WG deemed it necessary to conduct user studies. Two surveys were distributed in 2006. The first was a pilot study at the 2006 Semantic Technologies Conference (San Jose, California, USA). Most participants of this first study were either creators of semantic tools, including controlled vocabularies, taxonomies, and ontologies, or developers and managers of semantic technology systems. The second, an international survey among information professionals throughout the world, received about 800 responses. The majority of the participants were authority record creators, vocabulary creators and managers, catalogers, metadata librarians, and reference librarians.

Based on findings from these two surveys, which covered use scenarios for all user groups, four subject authority data user tasks were defined. Users may *find*, *identify*, and *select* a subject entity or entities and they may also

Fig. 1 FRSAD Working Group activities timeline.

Table 2 Comparison of the User Tasks Defined by FRBR, FRAD, and FRSAD

User Tasks		
FRBR (1998)	FRAD (2009)	FRSAD (2011)
Find entities of Group 1 that have entities from Groups 1, 2, and 3 as their subject	Find one entity or entities	Find one subject entity or entities
Identify	Identify an entity	Identify
Select		Select
Obtain	Contextualize , place in context, explore relationships Justify the form of an access point	Explore a subject domain or relationships

choose to *explore* a subject domain and its terminology as well as the relationships that exist among subjects. Table 2 provides a comparison of the user tasks defined in FRBR, FRAD, and FRSAD.

The four user tasks for subject authority data defined by FRSAD^[7] are

- **Find** one or more subjects and/or their appellations that correspond(s) to the user's stated criteria, using attributes and relationships
- **Identify** a subject and/or its appellation based on their attributes or relationships (i.e., to distinguish between two or more subjects or appellations with similar characteristics and to confirm that the appropriate subject or appellation has been found)
- **Select** a subject and/or its appellation appropriate to the user's needs (i.e., to choose or reject based on the user's requirements and needs)
- **Explore** relationships between subjects and/or their appellations (e.g., to explore relationships in order to understand the structure of a subject domain and its terminology)

As illustrated in Table 2, the *explore* user task is a new task introduced in FRSAD; whereas the *find*, *identify*, and *select* user tasks have been previously introduced in the FRBR and/or FRAD conceptual models.

In an attempt to verify the Group 3 entities originally defined by the FRBR model, the FRSAR WG collected comments found in published documents (refer to the next section, II.A) and conducted a small study to classify existing subject terms used by U.S. National Science Digital Library (NSDL) contributors into the categories based on FRBR entities (*Concept*, *Object*, *Event*, *Place*) plus *Time* and *Other*. These included about 3,000 terms assigned to NSDL metadata records. The terms were classified into six categories: concrete stuff, abstract stuff, event, time, place, and other. The study results indicated difficulties in the distinction between concrete and abstract concepts, as well as in categorizing named instances, which resulted in many subject terms being put into the "other" category. Findings of this study resulted in the development of FRSAD as a more abstract conceptual model.

II. THE FRSAD MODEL

A. The Development of the FRSAD Model

FRBR defines the many-to-many subject relationship between *work* and entities of Groups 1, 2, and 3 (Fig. 2). IFLA FRBR Group 3 entities are recognized as the subjects of *works* (i.e., the results of intellectual or artistic endeavor). They "represent an additional set of entities that serve as the subjects of *works*"^[3] (emphasis added), in addition to any of the Group 1 and 2 entities, which can also be subjects of *works*. Group 3 includes *concept* (an abstract notion or idea), *object* (a material thing), *event* (an action or occurrence), and *place* (a location).^[8]

From the time the FRSAR WG was formed, there seems to have been a general agreement in the FRBR research community that Group 3 entities should be revisited.^[9] The WG was considering several scenarios. In addition to enhancing the FRBR model based on Group 3 entities by adding "time," the approaches of other existing models were discussed. These models include the <indec> model,^[10] Ranganathan's facets,^[11] and the pragmatic list of entities developed by Buizza and Guerrini.^[12] These models present solid references for revising the FRBR conceptual model. The WG analyzed and discussed possible solutions based on each of these models, from conservative (making minor amendments of FRBR Group 3) to radical (proposing a completely new model). However, the WG found that none of the existing models and the ones based on them could be universal enough to reflect the needs of today's subject authority data, considering particularly different domains and subject access tools. In 2007, the WG shifted focus from the revision of the FRBR model to the development of a more general and abstract model, justified by the WG studies, which confirmed that there is no universally applicable and useful categorization of subjects. At the 2008 IFLA Québec meeting, the group concluded the development of the model as represented in the following figure (Fig. 3).

In this framework, instances of all entity types of all three entity groups, as defined by the FRBR conceptual model, have the potential to be the topics of a *work*. In

Fig. 2 Subject relationship as presented in FRBR 1988 final report Fig. 3.3 (Ref. 1, p. 15.).

other words, any instance of the Group 1, 2, and 3 entities can have an “is-subject-of” relationship with the *work*. The FRSAR Entity subgroup proposed a more abstract conceptual model. As presented in the following Figure 4, the model should be understood with two key points of view (Fig. 4):

1. This model confirms one of the basic relationships defined in FRBR: *WORK* has as subject *THEMA* / *THEMA* is subject of *WORK*.
 - a. *THEMA* is defined as any entity used as a subject of a work.^[13]
 - b. *THEMA* includes any FRBR entities—existing Group 1 and Group 2 entities and, in addition, all other subjects of *works*. This is a very abstract view, enabling us to model relationships and attributes on a more general and abstract level.

A Greek term (also used in Latin), *THEMA*, is used to avoid misunderstanding in translating the English term.

Fig. 3 FRSAD representation in 2008.

2. This model also proposes a new relationship: *THEMA* has appellation *NOMEN* / *NOMEN* is appellation of *THEMA*.
 - a. *NOMEN* is defined as any sign or sequence of signs (alphanumeric characters, symbols, sound, etc.) that a thema is known by, referred to, or addressed as.^[13]
 - b. Examples include “love,” “∞”, or “595.733.”

A Latin term, *NOMEN*, was chosen for the same reason as above.

This was a major breakthrough because, for many years, terms or labels representing concepts have been mixed with concepts in subject authority tools.

To simplify Figure 3, FRSAD model can be presented by the following illustration (Fig. 5):

Some important accents regarding the model:

- The “has as subject/is subject of” relationship is a many-to-many relationship. Any *work* can have more than one *thema*, and any *thema* can be the subject of more than one *work*.

- In general (i.e., in natural language or when mapping different vocabularies) the “has appellation/is appellation of” relationship is also a many-to-many relationship. A *thema* has one or more *nomen* and there may be a *nomen* referring to more than one *thema*.
- It is important, however, to note that, in a given controlled vocabulary and within a domain, a *nomen* should be an appellation of only one *thema*.

Attributes of *thema* and *nomen*, relationships between *themas* and between *nomens*, as well as *thema*-to-*nomen* relationships are all discussed in detail in the FRSAD report.

An Overview of the FRSAD Model

Presented below is an overview of the constructs in the FRSAD model: 1) the entities (*thema* and *nomen*), 2) the attributes of *thema* and *nomen* (Table 3), and 3) relationships between the entities (*work*–*thema* and *thema*–*nomen*)

Fig. 4 FRSAD’s relation to FRBR.

Fig. 5 FRSAD conceptual model.

and within the entities (*thema–thema* and *nomen–nomen*) (Table 4).

The importance of the *THEMA–NOMEN* model for the subject authority data is to separate *themas* from what they are known by, referred to, or addressed as. This enables us to define attributes and relationships for the appellation separately.

It is therefore up to application profiles, developed to support particular implementations, to deal with the complex *themas* by specifying the rules for creation of

complex *nomens*. Rules guide creation of subject heading strings or faceted classification. This is therefore another area that is language/domain/system specific and should be addressed within application profiles.

Differences between FRBR, FRAD, and FRSAD

Two models, FRAD and FRSAD, are complementing and further developing some aspects of FRBR. All three have been labeled the “FRBR family,” suggesting that they all

Table 3 Entities and Attributes in FRSAD

Thema	
Type:	Entity
Definition:	Any entity used as a subject of a <i>work</i> .
Attributes:	Type of <i>thema</i> The category to which a <i>thema</i> belongs in the context of a particular KOS. Scope note A text describing and/or defining the <i>thema</i> or specifying its scope within the particular subject authority system.
Nomen	
Type:	Entity
Definition:	Any sign or sequence of signs (alphanumeric characters, symbols, sound, etc.) that a <i>thema</i> is known by, referred to, or addressed as.
Attributes:	Type of <i>nomen</i> Category to which the <i>nomen</i> belongs. Scheme The scheme in which the <i>nomen</i> is established, including value-encoding schemes (particular subject heading lists, thesauri, classification systems, name authority lists, etc.) and syntax encoding schemes (standards for encoding dates, etc.). Reference source of <i>nomen</i> The source in which the <i>nomen</i> is found. It may also be modeled as a relationship with the appropriate Group 1 entity (<i>work</i>, <i>expression</i>, <i>manifestation</i>). Representation of <i>nomen</i> The data type in which the <i>nomen</i> is expressed. Language of <i>nomen</i> The language in which the <i>nomen</i> is expressed. Script of <i>nomen</i> The script in which a <i>nomen</i> is expressed. Script conversion The rule, system, or standard used to render the <i>nomen</i> in a different representation. Form of <i>nomen</i> Any additional information that helps to interpret the <i>nomen</i>. Time of validity of <i>nomen</i> The time period in which a particular instance of a <i>nomen</i> is/was used or is/was valid within a subject vocabulary system. Audience The community or user group for which this <i>nomen</i> is the preferred form. Status of <i>nomen</i> The status of a particular <i>nomen</i> in a subject authority system.

are considered parts of a larger general model. There exist some differences among them due to different modeling decisions made during their independent development over time. At the time of writing, the FRBR Review Group is working on the harmonization of FRBR, FRAD, and FRSAD. The project was completed in 2017 with a the new IFLA Library Reference Model (LRM), replacing all three FR family models.

Relationship of FRSAD with FRBR

The FRSAR WG follows FRBR in the methodology, specification, and presentation of entities and relationships. The “has as subject” (many-to-many) relationship, established between the *work* and the entity(ies) representing the aboutness of the *work*, is kept in its entirety in FRSAD. The four areas where some differences were introduced in FRSAD are as follows:

- The “Explore” task is added.
- *Thema* is introduced as a superclass of all entities that can be subjects of a *work*.
- No entity types are explicitly predefined in Group 3.
- *Nomen* is introduced (including attributes and relationships) and is defined as a separate entity instead of an attribute of an entity.

In Fig. 3.3 of the FRBR report, the depicted “subject” relationship has three boxes representing all three groups of entities, respectively, on the right side of the “has as subject” relationship. FRSAD has developed this further by creating a superclass (*thema*), thus enabling the modeling of the “has as subject” relationship on a more general level. *Thema* includes Group 1, Group 2, and all other entities that can be the subjects of a *work*. Therefore, the subject relationship can easily be modeled as “*work* has as subject *thema*.”

FRSAD introduces a differentiation between a thing itself and its appellation. The appellation (name, label, etc.) is often modeled as an attribute of the entity it refers to (e.g., in FRBR). While seemingly simpler, such an approach makes it impossible to introduce the attributes (e.g., language, script) of appellations and relationships between appellations (e.g., between a former and a latter name). In FRSAD, *Nomen* is introduced as an entity to enable appropriate modeling.

Relationship of FRSAD with FRAD

The FRANAR WG was established in 1999 with the mandate to develop further FRBR in the area of authority files. Later, the decision was made by FRANAR to focus on Group 2 entities and *work* only. As a consequence, the FRSAR WG was established to cover the “has as subject” relationship and the appropriate entities. The FRAD and FRSAD models were therefore developed independently. The most significant differences are as follows:

- User tasks: “Contextualize” and “Justify” in FRAD vs. “Explore” in FRSAD
- *Subject* as an attribute of *work* in FRAD
- *Name* in FRAD vs. *Nomen* in FRSAD
- *Name*, *Identifier*, and *Controlled access point* as separate entities in FRAD vs. values of the attribute “Type of *Nomen*” in FRSAD

- *Rules* and *agency* as new entities in FRAD and not explicitly modeled in FRSAD

FRSAD’s user task “explore” is a generalization of FRAD’s “contextualize” and expresses better the user task of browsing, getting acquainted, becoming familiar with, and discovering. FRAD “justify,” on the other hand, is a task of information professionals and not end users. It is an important task on its own, but in the context of metadata creation and not metadata use.

Although similar at first glance, FRAD’s entity *name* (defined as “a character or group of words and/or characters by which an entity is known in the real world”) and FRSAD’s entity *nomen* are different. The FRSAD *nomen* is a more general entity, comprising any (textual or other) appellation both in the real world and in artificial systems. In relation to FRAD, *nomen* is a superclass of FRAD *name*, *identifier*, and *controlled access point*.

Rules and *agency* are not specifically modeled in FRSAD, because again they apply to the cataloging process. If needed, *rules* (which are applied in all phases of cataloging, not merely in creation of controlled access points) should be considered instances of *work*. *Agencies*, which apply the rules, should be considered instances of *corporate body*. If modeled, they are in a relationship with the attribute assignment event.

III. DISCUSSION ON FRSAD MODEL

Following the release of the FRSAD Draft Report for worldwide review in June 2009, the WG received a number of comments. Four major comment categories are presented and discussed below.

FRSAD Terminology

While many explicitly praised the choice of Latin terms for the main entities of FRSAD, some expressed concern about this choice: Latin terminology was labeled as old fashioned, confusing, and presumptuous. Meanwhile, no real alternative was suggested. The choice of Latin terms is explained in the FRSAD Final Report^[14]:

The Working Group chose Latin terms, *thema* (plural *themata* or *themas*) and *nomen* (plural *nomina* or *nomens*), because they have no pre-existing meaning in our context, are culturally neutral, and do not require translation. For *thema*, other possible (English) terms include “subject,” “topic,” and “concept”; however, even discussions within the WG proved that there are very different views on granularity (some see “subject” and “topic” as synonyms, while others see “topic” as a component of “subject”). The WG needed to distinguish *thema* from the previously defined FRBR entity *concept* because *thema* is a superclass of all FRBR entities (to be explained in the next

section). For *nomen*, it is the case that the term “name” is often considered synonymous to proper name. In addition, the WG needed to distinguish *nomen* from the FRAD entity *name* because *nomen* includes FRAD entities *name*, *identifier*, and *controlled access point*.

The terminology problems would be similar in languages other than English. The choice of Latin, which does not have to be translated, has already been tested in translating FRSAD presentations into all official IFLA languages. Translators reported no problems.

FRSAD Is General and Abstract

Soon after FRBR was published, Strunck^[15] noted, “Some students find it unnecessarily complicated to operate with the abstract entities of the model as you cannot study these entities per se. They find the definitions of the entities to be academic and airy.” The problem seems to persist with FRSAD.

The library community has no tradition of conceptual models; FRBR is the first of its kind. It is therefore understandable that practicing librarians are often focusing on detailed rules and not on the big picture. Modeling is difficult and cannot be mastered without some education. It would therefore be necessary to include those topics in the curricula of library schools and continuing education opportunities for professionals. Not only will this enable professionals to understand and contribute to the development of FRBR and related models, it will also help them to more efficiently communicate with developers of computer tools.

FRSAD’s Applicability in Libraries

Some have commented that FRSAD does not closely model the current cataloging practice and is not directly applicable to Library of Congress Subject Headings (LCSH). While this is true, it is also intentional. A lot of developments in the area of subject access, including the development of different knowledge organization systems, are currently conducted outside the library domain. In addition, the mission and purpose of a conceptual model is not to blindly model the current practice but rather to question it and propose improved solutions in order to pave the way for better, more popular, and widely used bibliographic information systems.

The FRSAD Final Report addressed the applicability issue by including an appendix that provides examples using a variety of existing subject authority systems, including *The USP Dictionary of U.S. Adopted Names and International Drug Names*, *Getty Thesaurus of Geographic Names*, and *Medical Subject Headings (MeSH)*^[16].

This appendix provides examples found in implementations of existing subject authority systems through the perspective of the FRSAD model, presented

in four parts: 1) existing models of *thema* types; 2) *thema-thema* relationships presented in subject authority data (both in individual vocabularies and cross-schemes); 3) same *thema* represented by *nomens* from different schemes; and 4) examples of display records from controlled vocabularies or subject authority systems.

COMPLEXITY OF *THEMA*

According to these comments, *thema* is too general and does not appropriately cover the difference between simple and complex *themas*.

Although everybody intuitively understands that some topics are simpler than others (e.g., “cats” vs. “winter fishing in the Cuyahoga River”), a proper definition of complexity is difficult. It seems that we mostly associate the complexity of a *thema* with the complexity of its *nomen*. The problem is addressed in the FRSAD Final Report^[17]:

Themas can vary substantially in complexity or simplicity. Depending on the circumstances (the subject authority system, user needs, the nature of the *work*, etc.) the aboutness of a *work* can be expressed as a one-to-one relationship between the *work* and the *thema*; this means that the totality of the aboutness is encompassed in a single *thema*. In other circumstances the relationship is one-to-many, meaning that the aboutness of the *work* is captured in two or more *themas*. It is virtually impossible to define what the universal “atomic” level of a *thema* might be, because any *thema* can be fragmented further. The argument can be reversed: simple *themas* may be combined or aggregated, resulting in more complex *thema(s)*. In each particular implementation the atomic level is specified and rules guide the creation of *nomens* for complex *themas*.

IV. APPLICATIONS OF FRSAD MODEL

Developed as a general conceptual model that focuses on the subject relationship, FRSAD provides a theoretical framework for all knowledge organization structures, systems, and services (KOS) and their data models. FRSAR WG aimed to develop this model in order to assist in an assessment of the potential for international sharing and use of subject authority data both within the library sector and beyond.

Because the *thema* entity class includes anything that is or has the potential of being or becoming a subject, not restricted to actual subjects of *works* within a particular collection, the FRSAD model is applicable in a wide range of activities related to the development and management of KOS. FRSAD’s modeling of *nomen* as an entity also allows tremendous flexibility for modeling attributes and attribute values for *nomens* representing *themas*. The WG

members have conducted a series of studies on the implementation of FRSAD for various KOS since the model was finalized, especially in controlled lists, subject headings systems, and thesauri, as well as taxonomies and classification systems. The studies have focused on the following issues^[18,19]:

- The granularity of *themas* in different KOS vocabularies.
- Representation of *themas* by various appellation forms in these KOS vocabularies. These can be seen from different perspectives: single, compound, or multiple-word terms; pre-coordinated or stand-alone; notations with captions or category labels, etc.
- FRSAD model for authority data in general (i.e., not restricted to subject authority data).
- The potential of FRSAD for multilingual and multicultural community needs.
- Approaches for handling vocabulary mapping in situations where vocabularies have or have not already applied the FRSAD model.

The studies conducted by the WG have also confirmed that the FRSAD model coincided with the works of a number of other efforts of standardization for KOS construction, publishing, and interoperating, particularly:

- ISO 25964-1:2011 Thesauri and interoperability with other vocabularies—Part 1: Thesauri for information retrieval (published in 2011)^[20]
- SKOS Simple Knowledge Organization System Reference. W3C Recommendation March 17, 2009^[21]
- SKOS Core Vocabulary Specification. W3C Working Draft May 10, 2005^[22]
- SKOS eXtension for Labels (SKOS-XL). In: SKOS Simple Knowledge Organization System Reference. W3C Recommendation March 17, 2009^[23]

Conceptual models and data models have been developed or enhanced by the working groups of these standards, each with particular implementation targets in mind. FRSAD WG conducted careful studies and mappings to these models; the results have been presented in several conferences. In general, the conceptualization of the relationship between a concept (*thema*) and the representations of the concept (*nomen(s)*) is consistent with all these models. As indicated previously, FRSAD added a new entity, *nomen*, to the FRBR family. This enables the modeling of *nomen* by defining its attributes as well as relationships between instances of a *nomen*. This important conceptualization can be found to have echoes in the data models of ISO 25964. It is also paralleled by the newer version of the SKOS, which supplements an eXtension for Labels (SKOS-XL) (SKOS Simple Knowledge Organization System Reference, 2009, Appendix B) specification in 2009. SKOS has been widely used by the

Linked Data datasets of subject authorities such as the *Library of Congress Subject Headings (LCSH)*, *Dewey Decimal Classification (DDC)*, *AGROVOC*, and *Eurovoc*, as well as name authorities such as the *Library of Congress Name Authority File (LCNAF)* and *Virtual International Authority File (VIAF)*.^[24]

Another important model FRSAD WG has studied is the Dublin Core Metadata Initiative (DCMI) Abstract Model, a DCMI Recommendation.^[25] The FRSAD model is consistent with the DCMI abstract model in the sense that FRSAD allows any *thema* to be independent of any *nomen*, including any syntax that a *nomen* may use. Furthermore, it will enable the sharing, linking, and reuse of subject authority data among not only the subject vocabularies themselves but also metadata resources.

These studies conducted by the WG and the fact that FRSAD complies with the models presented in ISO 25964, SKOS, and the DCMI Abstract Model provide proof that the FRSAD model can meet the needs of subject authority data in both the conventional information management environment and the emerging Linked Data environment.

Abstract

This entry presents a definition of fuzzy set theory and an overview of some applications to model flexible information retrieval systems. The entry focuses on a description of fuzzy indexing procedures defined to represent the varying significance of terms in synthesizing the documents' contents, the representation of structured documents so as to model a subjective view of document content, the definition of flexible query languages which allow the expression of soft selection conditions, and fuzzy associative retrieval mechanisms to model fuzzy pseudothesaurs, fuzzy ontologies, and fuzzy categorizations of documents.

INTRODUCTION

The objective of this entry is to provide an overview of some applications of fuzzy set theory to design flexible information retrieval systems (IRSs). The term “flexible” implies that we consider IRSs that can represent and manage the uncertainty, vagueness, and subjectivity, which are characteristic of the process of information searching and retrieval.

Consider the notions that index terms offer only an approximate and incomplete view of a document's content, that query languages (such as those incorporating Boolean logic) do not usually allow users to express vague requirements for specifying selection conditions that are tolerant to imprecision, and that a document's relevance to the user's query is a subjective and an imprecise notion. We show how imprecision, vagueness, and subjectivity can be managed within the formal framework of fuzzy set theory. This means that retrieval mechanisms capable of both modeling human subjectivity and of estimating the partial relevance of documents to a user's needs can be designed.

The retrieval process is introduced as a fuzzy multi-criteria decision-making (MCDM) activity in the presence of vagueness. Documents constitute the set of the alternatives described using weighted index terms. The query specifies a set of soft constraints on the document representations that are created via indexing. The retrieval mechanism performs a decision analysis in the presence of imprecision to rank the documents on the basis of their partial satisfaction of the soft constraints.

This entry is organized as follows: in the section on “Current Trends in IR,” the current trends and key issues in IR are discussed. In the section on “Fuzzy Retrieval Models,” an overview of the basic notions of fuzzy set theory to model flexible IRSs are presented. In the section on “Fuzzy Document Indexing,” a description of the traditional fuzzy document representation is first illustrated. In addition, both a fuzzy representation of documents structured into logical sections that can be adapted to the subjective needs of a user and a fuzzy representation of HTML documents are presented. In the section on “Flexible Querying,” a description of how the Boolean query language of IR can be extended so as to make it flexible and suitable to express soft constraints by capturing the vagueness of the user needs is presented. Both numeric and linguistic selection conditions are introduced to qualify term's importance, and it is shown how linguistic quantifiers are defined to specify soft aggregation operators of query terms. In the section on “Fuzzy Associative Mechanisms,” a description of how fuzzy sets can serve to define associative mechanisms to expand the functionalities of IRSs are presented. The focus of current research trends in IR is on the semantic web, i.e., the capability to represent concepts and to model their semantic relationships: fuzzy sets provide notions that can be applied to this purpose allowing to model either fuzzy pseudothesaurs and fuzzy ontologies and to build fuzzy categorizations of documents by fuzzy clustering techniques. In the section on “Fuzzy Performance Measures,” fuzzy performance measures for IRSs are introduced and the conclusion summarizes the main contents of this entry.

CURRENT TRENDS IN IR

In this section the current trends and the key issues in IR are introduced.

Current Trends in IR

Some of the current trends in IR research run the gamut in terms of expanding the discipline both to incorporate the latest technologies and to cope with novel necessities. In terms of novel necessities, with the diffusion of the Internet and the heterogeneous characteristics of users of search engines, which can be regarded as the new frontier of IR, a new central issue has arisen, generally known as the semantic web. It mainly consists in expanding IRSs with the capability to represent and manage the semantics of both user requests and documents so as to be able to account for user and document contexts. This need becomes urgent with cross-language retrieval, which consists in expressing queries in one language, and retrieving documents written in another language, that is what commonly happens when submitting queries to search engines. Cross language retrieval not only implies new works on text processing, e.g., stemming conducted on a variety of languages, new models of IR such as the development of language models, but also the ability to match terms in distinct languages at a conceptual level, by modeling their meaning.

Another research trend of IR is motivated by the need to manage multimedia collections with nonprint audio elements such as sound, music, and voice, and video elements such as images, pictures, movies, and animation. Retrieval of such elements can include consideration of both meta-data and content-based retrieval techniques. The definition of new IRSs capable to efficiently extract content indexes from multimedia documents, and to effectively retrieve documents by similarity or proximity to a query by example so as to fill the semantic gap existing between low-level syntactic index matching and the semantics of multimedia document and query are still to come.

In addition, modern computing technology, including storage media, distributed and parallel processing architectures, and improved algorithms for text processing and for retrieval, has an effect on IRSs. For example, improved string searching algorithms have improved the efficiency of search engines. Improved computer networks have made the Internet and the World Wide Web a possibility. Intelligent agents can improve retrieval in terms of attempting to customize and personalize it for individual users. Moreover, great improvements have been made in retrieval systems interfaces based on human-computer interface research.

These novel research trends in IR are faced by turning to technologies such as natural language processing, image processing, language models, artificial intelligence, and automatic learning.

Also fuzzy set theory can play a crucial role to define novel solutions to these research issues since it provides suitable means to cope with the needs of the semantic web,^[1,2] e.g., to model the semantic of linguistic terms so as to reflect their vagueness and subjectivity and to compute degrees of similarity, generalization, and specialization between their meanings.

Key Issues in IR

Modeling the concept of relevance in IR is certainly a key issue, perhaps the most difficult one, and no doubt the most important one. What makes a document relevant to a given user is still not fully understood, specifically when one goes beyond topicality (i.e., the matching of the topics of the query with the topics of the document). Of course, this leads to the realization that relevance is gradual and subjective.

A second key issue is the representation of the documents in a collection, as well as the representation of users' information needs, especially for the purpose of matching documents to the queries at a "semantic" level. This implies introducing incompleteness, approximation, and managing vagueness and imprecision.

Finally, a key issue is how to evaluate properly an IRS's performance. Here, too, one sees imprecision.

IMPRECISION, VAGUENESS, UNCERTAINTY, AND INCONSISTENCY IN IR

Very often the terms imprecision, vagueness, uncertainty, and inconsistency are used as synonymous concepts. Nevertheless when they are referred to qualify a characteristic of the information they have a distinct meaning.^[3] Since IR has to do with information, understanding the different meanings of imprecision, vagueness, uncertainty, and inconsistency allows to better understanding the perspectives of the distinct IR models defined in the literature.

Vagueness and imprecision are related to the representation of the information content of a proposition. For example, in the information request, "find *recent* scientific chapters dealing with the *early* stage of infectious diseases by HIV," the terms *recent* and *early* specify vague values of the publication date and of the temporal evolution of the disease, respectively. The publication date and the phase of an infectious disease are usually expressed as numeric values; their linguistic characterization has a coarser granularity with respect to their numeric characterization. Linguistic values are defined by terms with semantics compatible with several numeric values on the scale upon which the numeric information is defined. Imprecision is just a case-limit of vagueness, since imprecise values have a full compatibility with a subset of values of the numeric reference scale.

There are several ways to represent imprecise and vague concepts. Indirectly, by defining similarity or proximity relationships between each pair of imprecise and vague concepts.

If we regard a document as an imprecise or vague concept, i.e., as bearing a vague content, a numeric value computed by a similarity measure can be used to express the closeness of any two pairs of documents. This is the way of dealing with the imprecise and vague document and query contents in the vector space model of IR. In this context the documents and the query are represented as points in a vector space of terms and the distances between the query and the documents points are used to quantify their similarity.

Another way to represent vague and imprecise concepts is by means of the notion of fuzzy set. The notion of a fuzzy set is an extension to normal set theory.^[4] A set is simply a collection of objects. A fuzzy set (more properly called a fuzzy subset) is a subset of a given universe of objects, where the membership in the fuzzy set is not definite. For example, consider the idea of a person being middle-aged. If a person's age is 39, one can consider the imprecision of that person being in the set of middle-aged people. The membership function, μ , is a number in the interval $[0, 1]$ that represents the degree to which that person belongs to that set. Thus, the terms *recent* and *early* can be defined as fuzzy subsets, with the membership functions interpreted as compatibility functions of the meaning of the terms with respect to the numeric values of the reference (base) variable. In Fig. 1, the compatibility function of the term *recent* is presented with the numeric values of the time-scale measured in years. Note that here a chapter that has a publication date of the current year or 1 year previous is perfectly *recent*; however, the extent to which a chapter remains *recent* declines steadily over the next 2 years until chapters older than 3 years have no sense of being *recent*.

In the next sections we will see how the notion of fuzzy set has been used in the IR context to represent the vague concepts expressed in a flexible query for specifying soft selection conditions of the documents.

Uncertainty is related to the truth of a proposition, intended as the conformity of the information carried by the proposition with the considered reality. Linguistic

Fig. 1 Semantics of the term “recent” referring to the publication date of a scientific chapter. CD, current date; y, years.

expressions such as “probably” and “it is possible that” can be used to declare a partial lack of knowledge about the truth of the stated information.

Further, there are cases in which information is affected by both uncertainty and imprecision or vagueness. For example, consider the proposition “probably document d is relevant to query q .” Possibility theory^[5,6] together with the concept of a linguistic variable defined within fuzzy set theory^[7] provide a unifying formal framework to formalize the management of imprecise, vague, and uncertain information.^[8]

However, the same information content can be expressed by choosing a trade-off between the vagueness and the uncertainty embedded in a proposition. For example, one can express the content of the previous proposition by a new one “document d is more or less relevant to query q .” In this latter proposition, the uncertain term *probably* has been eliminated, but the specificity of the vague term *relevant* has been reduced. In point of fact, the term *more or less relevant* is less specific than the term *relevant*. A dual representation can eliminate imprecision and augment the uncertainty, like in the expression “it is *not completely probable* that document d fully satisfies the query q .”

One way to model IR is to regard it as an uncertain problem.^[9]

On the basis of what has been said about the trade-off between uncertainty and vagueness to express the same information content, there are two alternative ways to model the IR activity. One possibility is to model the query evaluation mechanism as an uncertain decision process. Here the concept of relevance is considered binary (crisp) and the query evaluation mechanism computes the probability of relevance of a document d to a query q . Such an approach, which does model the uncertainty of the retrieval process, has been introduced and developed by probabilistic IR models.^[10–12] Another possibility is to interpret the query as the specification of soft “elastic” constraints that the representation of a document can satisfy to an extent, and to consider the term *relevant* as a gradual (vague) concept. This is the approach adopted in fuzzy IR models.^[9,13] In this latter case, the decision process performed by the query evaluation mechanism computes the degree of satisfaction of the query by the representation of each document. This satisfaction degree, called the retrieval status value (RSV), is considered as an estimate of the degree of relevance (or is at least proportional to the relevance) of a given document with respect to a given user query. An RSV of 1 implies maximum relevance; an RSV value of 0 implies absolutely no relevance. And, an RSV value in the interval $[0, 1]$ implies an intermediate level or degree of relevance. For example, an RSV value of 0.5 could imply an average degree of relevance.

Inconsistency comes from the simultaneous presence of contradictory information about the same reality. An example of inconsistency can be observed when submitting

the same query to several IRSs that adopt different representations of documents and produce different results. This is actually very common and often occurs when searching for information over the Internet using different search engines. To solve this kind of inconsistency, some fusion strategies can be applied to the ranked lists each search engine produces. In fact, this is what metasearch engines do.^[14,15]

In this entry, we analyze the representation and management of vagueness as a means of improving the flexibility of IRSs. In particular, we will focus on the modeling of vagueness and in fuzzy IR models.

The document representation based on a selection of index terms is invariably incomplete. When synthesizing the content of a text manually by asking an expert to select a set of index terms, one introduces subjectivity in the representation. On the other hand, automatic full-text indexing introduces imprecision since the terms are not all fully significant in characterizing a document's content. However, these terms can have a partial significance that might also depend upon the context in which they appear, i.e., which document component.

In the query formulation, users often only have a vague idea of the information for which they are looking. Users therefore find it difficult to translate their needs into a precise request using a formal query language such as one employing Boolean logic.

A flexible IRS should be capable of providing more detailed and rich representations of documents and of interpreting vague queries in order to perform retrieval processes that tolerate, and account for, this vagueness.

FUZZY RETRIEVAL MODELS

Fuzzy retrieval models have been defined in order to reduce the imprecision that characterizes the Boolean indexing process, to represent the user's vagueness in queries, and to deal with discriminated answers estimating the partial relevance of the documents with respect to queries. Extended Boolean models based on fuzzy set theory have been defined to deal with one or more of these aspects.^[16–24] Surveys of fuzzy extensions for IRSs and of fuzzy generalizations of the Boolean retrieval model can be found in Kraft^[9] and Bordogna.^[13]

Fuzzy “knowledge-based” models^[25,26] and fuzzy associative mechanisms^[27–30] have been defined to cope with the incompleteness that characterizes either the representation of documents or the users' queries. Miyamoto^[31] illustrates a wide range of methods to generate fuzzy associative mechanisms.

It has been speculated that Boolean logic is passé, out of vogue. Yet, researchers have employed p-norms in the vector space model or Bayesian inference nets in the probabilistic model to incorporate Boolean logic into those models. In addition, the use of Boolean logic to separate a

collection of records into two disjoint classes has been considered, e.g., using the one-clause-at-a time (OCAT) methodology.^[32] Moreover, even now retrieval systems such as Dialog and Web search engines such as Google allow for Boolean connectives. It should come as no surprise, therefore, to see extensions of Boolean logic based upon fuzzy set theory for IR.

It is noteworthy that most of the research on fuzzy retrieval has been conducted by a relatively few scholars. Moreover, that research has focused upon theoretical models, focusing primarily upon text retrieval, so that precious little testing has to date been conducted.

Extensions of Fuzzy Boolean Retrieval Models

The fuzzy retrieval models have been defined as generalizations of the classical Boolean model. These allow one to extend existing Boolean IRSs without having to redesign them. This was first motivated by the need to be able to produce proper answers in response to the queries. In essence, the classical Boolean IRSs apply an exact match between a Boolean query and the representation of each document. This document representation is defined as a set of index terms. These systems partition the collection of documents into two sets, the retrieved documents and the rejected (non-retrieved) ones. As a consequence of this crisp behavior, these systems are liable to reject useful items as a result of too restrictive queries, as well as to retrieve useless material in reply to queries.^[33]

The softening of the retrieval activity in order to rank the retrieved items in decreasing order of their relevance to a user query can greatly improve the effectiveness of such systems. This objective has been approached by extending the Boolean models at different levels. We shall consider those levels in order to model retrieval using a MCDM model that allows the expression of the users' queries as soft constraints and produce discriminated answers.

Fuzzy techniques for documents' indexing

The aim here is to provide more specific and exhaustive representations of each document's information content. This means improving these representations beyond those generated by existing indexing mechanisms. We shall introduce the fuzzy interpretation of a weighted document representation and then later introduce a fuzzy representation of documents structured in logical sections that can be adapted to a user that has subjective criteria for interpreting the content of documents.^[17] In this same vein, we shall describe an indexing procedure for HTML documents.^[34]

Definition of flexible query languages

The objective here is to define query languages that are more expressive and natural than classical Boolean logic. This is done in order to capture the vagueness of user

needs as well as to simplify user–system interaction. This has been pursued with two different approaches. First, there has been work on the definition of soft selection criteria (soft constraints), which allow the specification of the different importance of the search terms. Query languages based on numeric query term weights with different semantics have been first proposed as an aid to define more expressive selection criteria.^[18,21,22,24,35] An evolution of these approaches has been defined that introduces linguistic query weights, specified by fuzzy sets such as *important* or *very important*, in order to express the different vague importance of the query terms.^[36] Second, there is the approach of introducing soft aggregation operators for the selection criteria, characterized by a parametric behavior which can be set between the two extremes of intersection (AND) and union (OR) as adopted in Boolean logic. Boolean query languages have been extended and generalized by defining aggregation operators as linguistic quantifiers such as *at least k* or *about k*.^[16]

As we shall see, the incorporation of weighted document representations in a Boolean IRS is a sufficient condition to improve the system via a ranking capability. As a consequence of this extension, the exact matching that is employed by a classical Boolean IRS is softened using a partial matching mechanism that evaluates the degree of satisfaction of a user's query for each document. This degree of satisfaction is the RSV that is used for ranking.

Fuzzy Associative Mechanisms

These associative mechanisms allow to automatically generating fuzzy pseudothesaurs, fuzzy ontologies, and fuzzy clustering techniques to serve three distinct but compatible purposes. First, fuzzy pseudothesaurs and fuzzy ontologies can be used to contextualize the search by expanding the set of index terms of documents to include additional terms by taking into account their varying significance in representing the topics dealt with in the documents. The degree of significance of these associated terms depends on the strength of the associations with a document's original descriptors. Second, an alternative use of fuzzy pseudothesaurs and fuzzy ontologies is to expand the query with related terms by taking into account their varying importance in representing the concepts of interest. The importance of an additional term is dependent upon its strength of association with the search terms in the original query. Third, fuzzy clustering techniques, where each document can be placed within several clusters with a given strength of belonging to each cluster, can be used to expand the set of the documents retrieved in response to a query. Documents associated with retrieved documents, i.e., in the same cluster, can be retrieved. The degree of association of a document with the retrieved documents does influence its RSV. Another application of fuzzy clustering in IR is that of providing an alternative way, with respect to the usual ranked list, of presenting the results of a search.

FUZZY DOCUMENT INDEXING

In order to increase the effectiveness of IRSs, the indexing process plays a crucial role. In fact, it is not sufficient to provide IRSs with powerful query languages or sophisticated retrieval mechanisms to achieve effective results if the representation of documents oversimplifies their information content.

Vector Space, Probabilistic, and Generalized Boolean Indexing

The vector space model and the probabilistic models generally adopt a weighted document representation, which has improved the Boolean document representation by allowing the association of a numeric weight with each index term.^[10,33] The automatic computation of the index term weights is based on the occurrences count of a term in the document and in the whole archive.^[37–39] In this case, the indexing mechanism computes for each document d and each term t a numeric value by means of a function F . An example of F which has the index term weight increasing with the frequency of term t in document d but decreasing with the frequency of the term in all the documents of the archive is given by

$$F(d, t) = tf_{dt} \times g(IDF_t) \quad (1)$$

where

- tf_{dt} is a normalized term frequency, which can be defined as:

$$= tf_{dt} = \frac{OCC_{dt}}{MAXOCC_d};$$

- OCC_{dt} is the number of occurrences of t in d ;
- $MAXOCC_d$ is the number of occurrences of the most frequent term in d ;
- IDF_t is an inverse document frequency which can be defined as: IDF_t

$$IDF_t = \log \frac{N}{NDOC_t};$$

- N is the total number of documents in the archive;
- $NDOC_t$ is the number of documents indexed by t ; and
- g is a normalizing function.

The computation of IDF_t is particularly costly in the case of large collections which are updated online.

The definition of such a function F is based on a quantitative analysis of the text, which makes it possible to model the qualitative concept of significance of a term in describing the information carried by the text. The adoption of weighted indexes allows for an estimate of the

relevance, or of the probability of relevance, of documents to a query.^[10,33]

Based on such an indexing function, and by incorporating Boolean logic into the query, the first fuzzy interpretation of an extended Boolean model has been to adopt a weighted document representation and to interpret it as a fuzzy set of terms.^[40] From a mathematical point of view, this is a quite natural extension: the concept of the significance of index terms in describing the information content of a document can then be naturally described by adopting the function F , such as the one defined by Zadeh^[5] as the membership function of the fuzzy set representing a document's being in the subset of concepts represented by the term in question. Formally, a document is represented as a fuzzy set of terms: $R_d = \sum_{t \in T} \mu_{R_d}(t)/t$ in which the membership function is defined as $\mu_{R_d}: D \times T \rightarrow \{0, 1\}$. In this case, $\mu_{R_d}(t) = F(d, t)$, i.e., the membership value, can be obtained by the indexing function F . We describe later that through this extension of the document representation, the evaluation of a Boolean query produces a numeric estimate of the relevance of each document to the query, expressed by a numeric score or RSV, which is interpreted as the degree of satisfaction of the constraints expressed in a query.

Fuzzy set theory has been applied to define new and more powerful indexing models than the one based on the function specified in Eq. 1. The definition of new indexing functions has been motivated by several considerations. First, these F functions do not take into account the idea that a term can play different roles within a text according to the distribution of its occurrences. Moreover, the text can be considered as a black box, closed to users' interpretation. Such users might naturally filter information by emphasizing certain subparts on the basis of their subjective interests. This outlines the fact that relevance judgments are driven by a subjective interpretation of the document's structure, and supports the idea of *dynamic* and *adaptive* indexing.^[17,41] By adaptive indexing, we mean indexing procedures which take into account the users' desire to *interpret* the document contents and to "build" their synthesis on the basis of this interpretation.

Fuzzy Representation of Structured Documents

We also consider the synthesis of a fuzzy representation of structured documents that takes into account the user needs.^[17] A document can be represented as an entity composed of sections (e.g., *title*, *authors*, *introduction*, and *references*). For example, a single occurrence of the term in the *title* indicates that the chapter is concerned with the concept expressed by the term, while a single occurrence in the *reference* suggests that the chapter refers to other publications dealing with that concept. The information role of each term occurrence depends then on the semantics of the subpart where it is located. This means that to the aim of defining an indexing function for

structured documents the single occurrences of a term may contribute differently to the significance of the term in the whole document. Moreover, the document's subparts may have a different importance determined by the users' needs. For example, when looking for chapters written by a certain author, the most important subpart would be the *author name*; while when looking for chapters on a certain topic, the *title*, *abstract*, and *introduction* subparts would be preferred.

Of course, when generating an archive of a set of documents, it is necessary to define the sections which one wants to employ to structure each document. The decision of how to structure the documents, i.e., the type and number of sections, depends on the semantics of the documents and on the accuracy of the indexing module that one wants to achieve. A formal representation of a document will be constituted using a fuzzy binary relation: with each pair <section, term>, a significance degree in the interval [0, 1] is computed to express the significance of that term in that document section. To obtain the overall significance degree of a term in a document, i.e., the index term weight, these values are *dynamically* aggregated by taking into account the indications that a user explicits in the query formulation. Other non-fuzzy approaches have also introduced the concept of boosting factor to emphasize differently the contribution of the index terms occurrences depending on the document sections to the overall index term weights. However these approaches compute *static* index term weights during the indexing process, without taking into account the user interpretation.

On the contrary, in the fuzzy approach the aggregation function is defined on two levels. First, the user expresses preferences for the document sections (the equivalent of the boosting factors), specifying those sections that the system should more heavily weight in order to take proper account of the evaluation of the relevance of a given document to that user's query. Second, the user should decide which aggregation function has to be applied for producing the overall significance degree. This is done by the specification of a linguistic quantifier such as *at least one*, *at least k*, or *all*.^[42] By adopting this document representation, the same query can select documents in different relevance order depending on the user's indicated preferences.

An indexing model has been proposed by which the occurrences of a term in the different documents' sections are taken into account according to specific criteria, and the user's interpretation of the text is modeled.^[17] During the retrieval phase, the user can specify the distinct importance (preference) of the sections and decide that a term must be present in *all* the sections of the document or in *at least a certain number* of them in order to consider the term fully significant. A section is a logical subpart identified by s_i , where $i \in 1, \dots, n$ and n is the total number of the sections in the documents. We assume here that an archive contains documents sharing a common structure.

Formally, a document is represented as a fuzzy binary relation:

$$R_d = \sum_{(t,s) \in T \times S} \mu_d(t,s)/(t,s) \quad (2)$$

The value $\mu_d(t,s) = F_s(d,t)$ expresses the significance of term t in section s of document d . A function $F_s: D \times T \rightarrow [0, 1]$ is then defined for each section s . The overall significance degree $F(d,t)$ is computed by combining the single significance degrees of the sections, the $F_s(d,t)$ s, through an aggregation function specified by the user. This function is identified by a fuzzy linguistic quantifier such as *all*, *at least k*, or *at least l*, which aggregates the significance degrees of the sections according to their importance values as specified by the user.

The criteria for the definition of F_s are based on the semantics of section s and are specified by an expert during the indexing of the documents. For example, for sections containing short texts or formatted texts, such as the *author* or *keywords*, a single occurrence of a term makes it fully significant in that section: in this case, it could be assumed that $F_s(d,t) = 1$ if t is present in s but 0 otherwise. On the other hand, for sections containing textual descriptions of variable length such as the *abstract* and *title* sections, $F_s(d,t)$ can be computed as a function of the normalized term frequency in the section as for example:

$$\mu_s(d,t) = tf_{dst} * IDF_t \quad (3)$$

in which IDF_t is the inverse document frequency of term t [see definition (5)], tf_{dst} is the normalized term frequency defined as:

$$tf_{dst} = \frac{OCC_{dst}}{MAXOCC_{sd}}$$

in which OCC_{dst} is the number of occurrences of term t in section s of document d and $MAXOCC_{sd}$ is a normalization parameter depending on the section's length so as not to underestimate the significance of short sections with respect to long ones. For example, this normalization parameter could be computed as the frequency of the term with the highest number of occurrences in the section.

To simplify the computation of this value, it is possible to heuristically approximate it: during the archive generation phase, with an expert indicating the estimated percentage of the average length of each section with respect to the average length of documents ($PERL_s$). Given the number of occurrences of the most frequent term in each document d , $MAXOCC_d$, an approximation of the number of occurrences of the most frequent term in section s of document d is

$$MAXOCC_{sd} = PERL_s * MAXOCC_d$$

Term Significance

To obtain the overall degree of significance of a term in a document, an aggregation scheme of the $F_s(d,t)$ s values has been suggested, based on a twofold specification of the user.^[17] When starting a retrieval session, users can specify their preferences on the sections s by a numeric score $\alpha_s \in [0, 1]$ where the most important sections have an importance weight close to 1. Moreover, users can select a linguistic quantifier to specify the aggregation criterion; the quantifier can be chosen among *all* (the most restrictive one), *at least one* (the weakest one), or *at least k* which is associated with an intermediate aggregation criterion.

Within fuzzy set theory linguistic quantifiers used to specify aggregations are defined as ordered weighted averaging (OWA) operators.^[43] When processing a query, the first step accomplished by the system for evaluating $F(d,t)$ is the selection of the OWA operator associated with the linguistic quantifier lq , OWA_{lq} . When the user does not specify any preferences on the documents' sections, the overall significance degree $F(d,t)$ is obtained by applying directly the OWA_{lq} operator to the values $\mu_1(d,t), \dots, \mu_n(d,t)$:

$$F(d,t) = OWA_{lq}(\mu_1(d,t), \dots, \mu_n(d,t))$$

When distinct preference scores $\alpha_1, \dots, \alpha_n$ are associated with the sections, it is first necessary to modify the values $\mu_1(d,t), \dots, \mu_n(d,t)$ in order to increase the "contrast" between the contributions due to important sections with respect to those of less important ones. The evaluation of the overall significance degree $F(d,t)$ is obtained by applying the operator OWA_{lq} to the modified degrees $\alpha_1, \dots, \alpha_n$: $F(d,t) = OWA_{lq}(\alpha_1, \dots, \alpha_n)$.

We can now briefly sketch a comparison of the effectiveness of a system adopting a simple weighted representation versus a system with this structured weighted representation. In particular, the different rankings of two documents obtained by adopting the two different representations are outlined by an example. The two documents considered in the archive of CNR research projects contain the term "genoma." Fig. 2 shows the normalized frequency of "genoma" in the sections of the two documents; as it can be noticed, the term "genoma" has the same total number of occurrences in both documents. Since the normalization factors are the same, by applying F as defined in Eq. 1, the significance of "genoma" in both documents gets the same value $F(d_1, \text{genoma}) = F(d_2, \text{genoma}) = 0.8$. Fig. 3 shows the significance degrees for each section in which the term "genoma" occurs. These degrees are obtained using the fuzzy representation of structured documents; since the title and keywords sections are short texts, μ_{title} and $\mu_{keywords}$ are defined so as to take values in $\{0, 1\}$. After estimating that the objective section takes up averagely 30% of the documents' length, and the

Fig. 2 Normalized frequency of “genoma” in the sections of the two documents.

description section is around 40%, $\mu_{\text{objective}}$ and $\mu_{\text{description}}$ are defined.

When the user does not specify any criterion to aggregate the single degrees of the sections, a default aggregation operator is used.^[16,17] Since no importance is specified to differentiate the contributions of the sections, all of them are assumed to have the same importance weight of 1. Notice that the document d_1 , which contains “genoma” in the *keywords* and *title* sections is now considered more significant with respect to document d_2 that contains the term just in the *objectives* and *description* sections.

These results could be reversed if the user specifies that the presence of the term “genoma” in the *objectives* section is fundamental. Fig. 4 illustrates this situation, showing the modified degrees of significances of the sections when the user sets the aggregation criterion equal to at least 1 and $\alpha_{\text{objective}} = 1$, $\alpha_{\text{title}} = \alpha_{\text{keywords}} = \alpha_{\text{description}} = 0.5$, and $\alpha_i = 0$ otherwise.

The fact that the user can explicate the preferences on the section and the aggregation criterion by a linguistic quantifier allows a subjective interpretation of document content and gives the user the possibility of full control on the system behavior. This is not the case for other IR models, the probabilistic model (e.g., Bayesian updating of the probabilities as part of relevance feedback), and Rocchio’s relevance feedback mechanism for the vector space model, or even the calculation of the rank for Web pages retrieved by Google using PageRank. In these models the retrieval criteria remain implicit and are not observable directly by the user.

Fig. 3 Significance degrees of “genoma” in each section of the two documents.

Experimental Results

A comparison of the results produced by using the traditional fuzzy representation of documents and the fuzzy representation of structured documents can be found.^[17] In this experiment, a collection of 2500 textual documents about descriptions of CNR research projects has been considered. The indexing module of the prototypal IRS named DOMINO, used for the experiment, has been extended in order to be able to recognize in the documents any structure simply by specifying it into a definition file. In this way it is not necessary to modify the system when dealing with a new collection of documents with a different structure. The definition of the documents sections has been made before starting the archive generation phase. During this phase it was also necessary to specify the criteria by which to compute the significance degrees of the terms in each section. Two kinds of sections have been identified: the “structured” sections, i.e., the research code, title, research leader, and the “narrative” sections, containing unstructured textual descriptions, i.e., the project description and the project objective. It has been observed that while the values of precision remain unchanged in the two versions of the system, the values of recall are higher by using the structured representation than those obtained by using the traditional fuzzy representation.

We illustrate another approach which produces a weighted representation of documents written in HTML.^[34] An HTML document has a specific syntactic structure in which its subparts have a given format specified by the delimiting tags. In this context, tags are seen as syntactic elements carrying an indication of the importance of the associated text. When writing a document in HTML, an author associates varying importance to each of the different subparts of a given document by delimiting them by means of appropriate tags. Since a certain tag can be employed more than once, and in different positions inside the document, the concept of document subpart is not meant as a unique, adjacent piece of text. Such a structure is subjective and carries the interpretation of the document author. It can be applied in archives, which collect heterogeneous documents, i.e., documents with possibly different “logical” structures.

Fig. 4 Modified significance degrees of the term “genoma” in the documents sections.

When generating a HTML document, an author exploits the importance weights associated with different subparts of the text. If characters of different fonts are used, it is assumed that the larger the font, the more important the information carried by the text. Moreover, to use boldface or italics for characters generally means the highlighting of a portion of the text. Tags constitute then indicators of the importance of documents' subparts.

An indexing function has been proposed which provides different weights for the occurrences of a given term in the document, depending on the tags by which they are delimited.^[34] The overall significance degree $F(d, t)$ of a term t in a document d is computed by first evaluating the term significance in the different document tags, and then by aggregating these contributions. With each tag, a function $F_{\text{tag}}: D \times T \rightarrow [0, 1]$ is associated together an importance weight $\mu_{\text{tag}} \in [0, 1]$. Note that the greater is the emphasis of the text associated with a tag, the greater is its importance weight. A possible ranking of the considered tags has been suggested^[34] in decreasing order of tag importance. The definition of such a list is quite subjective, although based on objective assumptions suggested by commonsense. These rankings include notion such as a larger font for the characters in a portion of text yields greater importance of that portion of text, or text in boldface or italics or appearing in a list can be assumed as having a higher importance. Of course, other orderings could be defined.

To simplify the hierarchy of the tags, we see that certain tags can be employed to accomplish similar aims, so one can group them into different classes. It is assumed that the members of a class have the same importance weight. Text not delimited by any tag is included into the lowest class. A simple procedure to compute numeric importance weights starting from the proposed ranking can be achieved. The definition of F_{tag} follows the same mechanism as the previous approach.^[17] The following normalized frequency is now proposed:

$$F_{\text{tag}}(d, t) = \frac{\text{NOCC}_{\text{tag dt}}}{\text{MAXOCC}_{\text{tag d}}}$$

in which $\text{NOCC}_{\text{tag dt}}$ is the number of occurrences of term t inside tag in document d , and $\text{MAXOCC}_{\text{tag d}}$ is the number of occurrences of the most frequent term inside the tag.

Once the single significance degrees of a term into the tags have been computed, these have to be aggregated in order to produce an overall significance degree of the term into the document. In the aggregation all the significance degrees should be taken into account, so as to consider the contribution of each tag, modulated by their importance weights. To this aim a weighted mean can be adopted:

$$A(F_{\text{tag1}}(d, t), \dots, F_{\text{tagn}}(d, t)) = \sum_{i=1, \dots, n} F_{\text{tag i}}(d, t) * w_i$$

in which $\sum_{i=1, \dots, n} w_i = 1$. Starting from the list of tags in decreasing relative order of their importance, the numeric weights w_i are computed through a simple procedure. Assuming that tag_i is more important than tag_j iff $i < j$ (i and j being the positions of tag_i and tag_j respectively in the ordered list), the numeric importance weight w_i associated with tag_i can be computed as $w_i = (n - i + 1) / \sum_{i=1, \dots, n} i$.

In the computation of the overall significance degree $F(d, t)$, the inverse document frequency of term t could be taken into account:

$$F(d, t) = \left(\sum_{i=1, \dots, n} F_{\text{tag i}}(d, t) * w_i * g(\text{IDF}_t) \right)$$

in which the definition of $g(\text{IDF}_t)$ is given in formula (5).

FLEXIBLE QUERYING

A flexible query language is a query language that incorporates some elements of natural language so users have a simple, powerful, and yet subjective mechanism by which to express their information needs. Flexibility can also be a characteristic of the query evaluation mechanism to

allow a tuning of the query's concepts' semantics with respect to the document collection, the user's subjective statement of information need, and even the user's application domain. Linguistic variables provide a suitable framework to generalize, to represent, and to manage the linguistics of the query's concepts. Thus, this approach can be used to formalize the semantics of linguistic terms introduced in a Boolean query language.

Flexible query languages have been defined as generalizations of Boolean query languages that employ Boolean logic. Within the framework of fuzzy set theory, we have the idea of a softening of the rigid, crisp constraints of a Boolean condition being strictly true (a document has a keyword) or false (the document does not contain the keyword).

A flexible query consists of either or both of two soft components. First, there can be selection conditions interpreted as soft constraints on the significance of the index terms in each document representation. Second, there can be soft aggregation operators, which can be applied to the soft constraints in order to define compound selection conditions. The atomic selection conditions for individual terms are expressed by pairs $\langle \text{term}, \text{weight} \rangle$, in which the weight can be a numeric value in the interval $[0, 1]$ that is used to identify a soft constraint or the weight can be a linguistic value for the variable *importance*. The compound conditions for combining terms via Boolean logic are expressed by means of linguistic quantifiers used as aggregation operators.

Query Evaluation Mechanism

Query processing within retrieval can be interpreted as a decision-making activity. Its aim is to evaluate a set of alternatives or possible solutions, in this case a set of documents, based upon some criteria or selection conditions in order to select the optimal list (perhaps ranked) of documents in response to a user's query.

In the case of a Boolean query, the alternatives are the document representations as described based on the presence or absence of index terms or keywords. The selection conditions, as expressed by terms specified in a query, define a set of constraints requiring the presence or absence of these terms within a document's representation. These conditions are expressed connected by aggregation operators, i.e., the Boolean logic operators of AND, OR, and NOT. The decision process is performed through an exact matching function, which is strictly dependent on the system query language. This decision process evaluates the global satisfaction of the query constraints for each document representation. Relevance is modeled as a binary property of the documents with respect to the user's query.

Given a fuzzy approach to retrieval, query processing can be regarded as a decision activity affected by vagueness. In fact, the query can be seen as the specification of

a set of soft constraints, i.e., vague selection conditions, that the documents can satisfy to a partial extent. The documents described through the significance degrees of the index terms constitute the alternatives. The query evaluation mechanism is regarded as fuzzy decision process that evaluates the degree of satisfaction of the query constraints by each document representation by applying a partial matching function. This degree is the RSV and can be interpreted as the degree of relevance of the document to the query and is used to rank the documents. Then, as a result of a query evaluation, a fuzzy set of documents is retrieved in which the RSV is the membership value. In this case the definition of the partial matching function is strictly dependent on the query language, specifically on the semantics of the soft constraints.

A wish list of requirements that a matching function of an IRS must satisfy has been proposed.^[18,24] Included in this list is the separability property that the evaluation of an atomic selection condition for an individual term in a query should be independent of the evaluation of the other atomic components or their Boolean connectors. The matching function should be based solely upon a function evaluating atomic conditions. Following the calculation of these evaluations, one can then aggregate them based upon the Boolean operators in the query. It has been shown that this property guarantees a homomorphic mapping from the space of all single terms to the space of all possible Boolean queries using these terms.^[44] This property has been considered widely within fuzzy retrieval models, especially in the definition of flexible query languages.

By designing the partial matching mechanism from the bottom-up the separability property is ensured. First, each atomic selection condition or soft constraint in the query is evaluated by a function E for a given document. Then the aggregation operators are applied to the results starting from the inmost operator in the query to the outermost operator by a function E^* . This E function evaluates the soft constraints associated with the query atoms on the fuzzy set R_d representing each document, where these soft constraints are defined as fuzzy subsets. The membership value $\mu_{\text{atom}}(i)$ is the degree of satisfaction of the soft constraint associated with the atomic query atom , i.e., $E(\langle \text{atom} \rangle, d) = \mu_{\text{atom}}(F(d, t))$. In other words, E evaluates how well the term t , which has an indexing weight $F(d, t)$ for document d , satisfies the soft constraint specified by atom . The result of the evaluation is a fuzzy set, $\sum_{d \in D} \mu_{\text{atom}}(F(d, t)) / d$ in which $\mu_{\text{atom}}(F(d, t))$ is interpreted as the RSV of document d with respect to the query atom.

The function $E^*: D \times Q \rightarrow [0, 1]$, where Q is the set of all the proper queries in the query language, evaluates the final RSV of a document, reflecting the satisfaction of the whole query. The definition of E^* depends strictly upon the structure of the query language, specifically upon the aggregation operators used to combine the atomic

components. The AND connective is classically defined as the minimum (min) operator, the OR connective as the maximum (max) operator, and the NOT connective as the one-minus (1−) or complement operator. These definitions preserve the idempotence property. A fuzzy generalization of the Boolean query structure has been defined in which the Boolean operators are replaced by linguistic quantifiers.^[16] In this context, linguistic quantifiers are used as aggregation operators to determine the degree of satisfaction for the soft constraints. They allow to improve as well as to simplify the expressiveness of the Boolean query language.

Query Weights

To render a Boolean query language to be more user-friendly and more expressive, one can extend the atomic selection conditions by introducing query term weights.^[22,23,45,46] An example of weighted query is the following: $\langle t_1, w_1 \rangle$ AND ($\langle t_2, w_2 \rangle$ OR $\langle t_3, w_3 \rangle$) in which t_1, t_2 , and t_3 , are search terms with numeric weights w_1, w_2 , and w_3 in the interval $[0, 1]$. These weights are implicitly given as being equal to 1 in the classical Boolean query language.

The concept of query weights raises the problem of their interpretation. Several authors have realized that the semantics of query weights should be related to the concept of the “importance” of the terms. Being well aware that the semantics of the query term weights influences the definition of the partial matching function, specifically of the E function, different semantics for the soft constraint imposed by a pair $\langle t, w \rangle$ have been proposed in the literature trying to satisfy as much as possible properties of the wish list, in particular the separability property.

Early on, query weights were interpreted as a relative importance weight where the separability property does not hold. Two distinct definitions of E have been proposed for conjunctive and disjunctive queries, respectively.^[22,47] Later, other models^[23,24,46] used an interpretation of the query weights w as a threshold on the index term weight or as an ideal index term weight.^[35,45]

Implicit query weights

The simplest extension of the Boolean model consists of the adoption of a weighted document representation but with a classical Boolean query language.^[40] This retrieval mechanism ranks the retrieved documents in decreasing order of their significance with respect to the user query. In this case, an atomic query consisting of a single term t is interpreted as the specification of a pair $\langle t, 1 \rangle$ in which $w = 1$ is implicitly specified. The soft constraint associated with $\langle t, 1 \rangle$ is then interpreted as the requirement that the index term weight be “close to 1” and its evaluation is defined as $\mu_w(F(d, t)) = F(d, t)$. This means that the desired

documents are those with maximum index term weight for the specified term t , i.e., index term weights closest to 1. This interpretation implies that the evaluation mechanism tolerates the under satisfaction of the soft constraint associated with $\langle t, 1 \rangle$ with a degree equal to $F(d, t)$.

Relative importance query weights

Here, query weights are interpreted as measures of the “relative importance” of each term with respect to the other terms in the query.^[22,47] This interpretation allows the IRS to rank documents so that documents are ranked higher if they have larger index term weights for those terms that have larger query weights. However, since it is not possible to have a single definition for the soft constraint μ_w that preserves the “relative importance” semantics independently of the Boolean connectors in the query, two distinct definitions of μ_w have been proposed, depending on the aggregation operators in the query. This approach, sadly, gives up the separability property. Two alternative definitions have been proposed for conjunctive and disjunctive queries.^[22,47] The first proposal^[22] yields

$$\begin{aligned}\mu_w(F(d, t)) &= wF(d, t) \text{ for disjunctive queries and} \\ \mu_w(F(d, t)) &= \max(1, F(d, t)/w) \text{ for conjunctive queries;}\end{aligned}$$

while the second proposal^[47] yields

$$\begin{aligned}\mu_w(F(d, t)) &= \min[w, F(d, t)] \text{ for disjunctive queries} \\ \mu_w(F(d, t)) &= \max[(1 - w), F(d, t)] \text{ for conjunctive queries}\end{aligned}$$

Notice that any weighted Boolean query can be expressed in disjunctive normal form (DNF) so that any query can be evaluated by using one of these two definitions.

Threshold query weights

To preserve the separability property, an approach treating the query weights as thresholds has been suggested.^[23,46] By specifying query weights as thresholds the user is asking to see all documents “sufficiently about” a topic. In this case, the soft constraint identified by the numeric query weight can be linguistically expressed as “more or less over w .” Of course, the lower the threshold, the greater the number of documents retrieved. Thus, a threshold allows a user to define a point of discrimination between under- and over satisfaction.

The simplest formalization of threshold weights has been suggested as a crisp threshold^[23]

$$\mu_w(F(d, t)) = \begin{cases} 0 & \text{for } F(d, t) < w \\ F(d, t) & \text{for } F(d, t) \geq w \end{cases}$$

In this case, the threshold defines the minimally acceptable document. Due to its inherent discontinuity, this formalization might lead to an abrupt variation in the number

of documents retrieved for small changes in the query weights. To remedy this, continuous threshold formalization has been suggested:^[46]

$$\mu_w(F(d, t)) = \begin{cases} P(w) * \frac{F(d, t)}{w} & \text{for } F(d, t) < w \\ P(w) + Q(w) * \frac{(F(d, t) - w)}{(1 - w)} & \text{for } F(d, t) \geq w \end{cases}$$

where $P(w)$ and $Q(w)$ might be defined as $P(w) = 1 + w/2$ and $Q(w) = 1 - w^2/4$.

For $F(d, t) < w$, the μ_w function measures the closeness of $F(d, t)$ to w ; for $F(d, t) \geq w$, $\mu_w(F(d, t))$ expresses the degree of over satisfaction with respect to w , and under satisfaction with respect to 1.

Ideal query weights

Another interpretation for the query weights has been defined.^[35,45] Here, the pair $\langle t, w \rangle$ identifies a set of ideal or perfect documents so that the soft constraint μ_w measures how well $F(d, t)$ comes close to w , yielding

$$\mu_w(F(d, t)) = e^{\ln(k) * (F(d, t) - w)^2}$$

The parameter k in the interval $[0, 1]$ determines the steepness of the Gaussian function's slopes. As a consequence, k will affect the strength of the soft constraint *close to w*. So, the larger the value of k is, the weaker the constraint becomes. This parametric definition makes it possible to adapt the constraint interpretation to the user concept of *close to w*.^[36] The retrieval operation associated with a pair $\langle t, w \rangle$ corresponds in this model to the evaluation of a similarity measure between the importance value w and the significance value of t in R_d : $w \approx F(d, t)$.

Comparisons of these query weight semantics

In order to analyze the results obtained by these different semantics associated with the query weight w , let us consider the archive represented by the fuzzy sets in Table 1. The rows are the documents, the columns are the terms, and the elements are the values of the index term weights, i.e., an element of row d_i and column t_j is the value $F(d_i, t_j)$. Let us consider the query: $q = \langle t_1, 1 \rangle \text{ AND } \langle t_2, 0.6 \rangle \text{ AND } \langle t_4, 0.2 \rangle$, as represented in Table 2.

Table 3 yields the results of the evaluation of q for each of the query weight semantics, assuming that the AND connective is evaluated using the MIN operator.

Table 1 Each row is a fuzzy set representing a document.

	t_1	t_2	t_3	t_4
d_1	1	0.9	1	0.2
d_2	0.7	0.6	0.3	0.8

Table 2 Query q (ANDed weighted pairs).

	t_1	t_2	t_4
q	1	0.6	0.2

Linguistic Query Weights

The main limitation of numeric query weights is their inadequacy in dealing with the imprecision which characterizes the concept of importance that they represent. In fact, the use of numeric query weights forces the user to quantify a qualitative and rather vague notion and to be aware of the weight semantics. Thus, a fuzzy retrieval model with linguistic query weights has been proposed^[36] with a linguistic extension of the Boolean query language based upon the concept of a linguistic variable.^[7] With this approach, the user can select the primary linguistic term "important" together with linguistic hedges (e.g., "very" or "almost") to qualify the desired importance of the search terms in the query. When defining such a query language the term set, i.e., the set of all the possible linguistic values of the linguistic variable *importance* must be defined. Such a definition depends on the desired granularity that one wants to achieve. The greater the number of the linguistic terms, the finer the granularity of the concepts that are dealt with. Next, the semantics for the primary terms must be defined. A pair $\langle t, \text{important} \rangle$, expresses a soft constraint $\mu_{\text{important}}$ on the term significance values (the $F(d, t)$ values). The evaluation of the relevance of a given document d to a query consisting solely of the pair $\langle t, \text{important} \rangle$ is based upon the evaluation of the degree of satisfaction of the associated soft constraint $\mu_{\text{important}}$.

The problem of giving a meaning to numeric weights reappears here in associating a semantic with the linguistic term *important*. The $\mu_{\text{important}}$ function is defined based on the ideal semantics of the numeric weight to yield^[36]

$$\mu_{\text{important}}(F(d, t)) = \begin{cases} e^{\ln(k) * (F(d, t) - i)^2} & \text{for } F(d, t) < i \\ 1 & \text{for } i \leq F(d, t) \leq j \\ e^{\ln(k) * (F(d, t) - j)^2} & \text{for } F(d, t) > j \end{cases}$$

We see that if $F(d, t)$ is less than the lower bound i or greater than the upper bound j , the constraint is under satisfied. The strength of the soft constraint $\mu_{\text{important}}$ depends upon both the width of the range $[i, j]$ and the value of the k parameter. The values i and j delimit the

Table 3 Results of query q in Table 2 referred to documents in Table 1.

Query weight semantics	d_1	d_2
Ideal index term weight	0.3	0.6
Relative importance	0.8	0.6
Threshold on index term weight	0.2	0

level of *importance* for the user. We note that as the value $|i - j|$ increases, the soft constraint becomes less precise. So, for the case of the ideal semantics of numeric query term weights, k determines the sharpness of the constraint in that as k increases, the constraint increases in fuzziness.

We can define the $\mu_{\text{important}}$ function based upon the threshold semantics to yield^[48]

$$\mu_{\text{important}}(F(d, t)) = \begin{cases} \frac{1+i}{2} * e^{\ln(k) * (F(d, t) - i)^2} & \text{for } F(d, t) < i \\ \frac{1+F(d, t)}{2} & \text{for } i \leq F(d, t) \leq j \\ \frac{1+j}{2} * \left(1 + \frac{F(d, t) - j}{2}\right) & \text{for } F(d, t) > j \end{cases}$$

We note that this compatibility function is continuous and nondecreasing in $F(d, t)$ over the interval $[0, 1]$. For $F(d, t) < i$, $\mu_{\text{important}}$ increases as a Gaussian function. For $F(d, t)$ in the interval $[i, j]$, $\mu_{\text{important}}$ increases at a linear rate. For $F(d, t) > j$, $\mu_{\text{important}}$ still increases, but at a lesser rate. The compatibility functions of non-primary terms, such as *very important* or *fairly important*, are derived by modifying the compatibility functions of primary terms. This is achieved by defining each linguistic hedge as a modifier operator. For example, the linguistic hedges are defined as translation operators in^[48] to yield

$$\mu_{\text{very important}}(x) = \mu_{\text{important}}(x)$$

$$\text{with } i_{\text{very}} = i + 0.2 \text{ and } j_{\text{very}} = j + 0.2 \text{ and } \forall x \in [0, 1].$$

$$\mu_{\text{averagely important}}(x) = \mu_{\text{important}}(x)$$

$$\text{with } i_{\text{averagely}} = i - 0.3 \text{ and } j_{\text{averagely}} = j - 0.3 \text{ and } \forall x \in [0, 1].$$

$$\mu_{\text{minimally important}}(x) = \mu_{\text{important}}(x)$$

$$\text{with } i_{\text{minimally}} = i - 0.5 \text{ and } j_{\text{minimally}} = j - 0.5 \text{ and } \forall x \in [0, 1].$$

in which i and j are values in $[0, 1]$ delimiting the range of complete satisfaction of the constraint $\mu_{\text{important}}$. With these definitions, any value $F(d, t)$ of the basic domain of the *importance* variable fully satisfies at least one of the constraints defined by the linguistic query terms.

In Herrera-Viedma^[49] a query language with linguistic query weights having heterogeneous semantics have been proposed so as to benefit of the full potential offered of fuzzy set to model subjective needs.

Linguistic Quantifiers to Aggregate the Selection Conditions

In a classical Boolean query language, the AND and OR connectives allow only for crisp (non-fuzzy) aggregations which do not capture any of the inherent vagueness of user information needs. For example, the AND used for aggregating M selection conditions does not tolerate the no satisfaction of but a single condition which could cause the no retrieval of relevant documents. To deal with this

problem, additional extensions of Boolean queries have been provided which involves the replacement of the AND and OR connectives with soft operators for aggregating the selection criteria.^[33,50,51]

Within the framework of fuzzy set theory, a generalization of the Boolean query language has been defined based upon the concept of linguistic quantifiers that are employed to specify both crisp and vague aggregation criteria of the selection conditions.^[16] New aggregation operators can be specified by linguistic expressions with self-expressive meaning, such as *at least k* and *most of*. They are defined to exist between the two extremes corresponding to the AND and OR connectives, which allow requests for *all* and *at least one of* the selection conditions, respectively. The linguistic quantifiers used as aggregation operators are defined by OWA operators.

Adopting linguistic quantifiers more easily and intuitively formulate the requirements of a complex Boolean query. For example, when desiring that *at least 2* out of the three terms “politics,” “economy,” and “inflation” be satisfied, one might formulate the Boolean query as:

(politics AND economy) OR (politics AND inflation)
OR (economy AND inflation)

However, a simpler one can replace this,

atleast2(politics,economy,inflation)

This new query language via the nesting of linguistic quantifiers supports the expression of any Boolean query. For example the query

<image> AND (<processing> OR <analysis>) AND <digital>

can be translated into the new, more synthetic and clear formulation:

all (<image>, *at least 1 of* (<processing>, <analysis>), <digital>).

A quantified aggregation function can be applied not only to single selection conditions, but also to other quantified expressions. Then, the E^* function evaluating the entire query yields a value in $[0, 1]$ for each document d in the archive D .

If S is the set of atomic selection conditions and Q is the set of legitimate Boolean queries over our vocabulary of terms, then the E^* function can be formalized by recursively applying the following rules

1. if $q \in S$ then $E^*(d, s) = \mu_w(F(d, t))$ in which $\mu_w(F(d, t))$ is the satisfaction degree of a pair $\langle t, w \rangle$ by document d with w being either a numeric weight or a linguistic weight.

2. if $q = \text{quantifier}(q_1, \dots, q_n)$ and $q_1, \dots, q_n \in Q$ then

$$E * (d, q) = \text{OWA}_{\text{quantifier}}(E * (d, q_1), \dots, E * (d, q_n))$$

3. $E^*(d, \text{NOT } q) = 1 - E^*(d, q)$

in which $\text{OWA}_{\text{quantifier}}$ is the OWA operator associated with *quantifier*.

The formal definition of the query language with linguistic quantifiers with the following quantifies has been generated^[16]

- *all* replaces AND.
- *at least k* acts as the specification of a crisp threshold of value k on the number of selection conditions and is defined by a weighting vector $w_{\text{at least } k}$ in which $w_k = 1$, and $w_j = 0$, for $i \leq k$ —noting that *at least 1* selects the maximum of the satisfaction degrees so that it has the same semantics of OR.
- *about k* is a soft interpretation of the quantifier *at least k* in which the k value is not interpreted as a crisp threshold, but as a fuzzy one so that the user is fully satisfied if k or more conditions are satisfied but gets a certain degree of satisfaction even if $k-1, k-2, \dots, 1$ conditions are satisfied—this quantifier is defined by a weighting vector $w_{\text{about } k}$ in which $w_i = \frac{i}{\sum_{j=1}^k j}$ for $i \leq k$, and $w_i = 0$ for $i > k$.
- *most of* is defined as a synonym of *at least $\frac{2}{3}n$* in which n is the total number of selection conditions.

With respect to non-fuzzy approaches that tried to simplify the Boolean formulations, the fuzzy approach subsumes the Boolean language, allows reformulating Boolean queries in a more synthetic and comprehensible way, and improves the Boolean expressiveness by allowing flexible aggregations.

Other authors have followed these ideas by proposing alternative formalization of linguistic query weights and flexible operators based on ordinal labels and ordinal aggregations,^[52] thus reducing the complexity of the evaluation mechanism.

FUZZY ASSOCIATIVE MECHANISMS

Associative retrieval mechanisms are defined to enhance the retrieval of IRSs. They work by retrieving additional documents that are not directly indexed by the terms in a given query but are indexed by other, related terms, sometimes called associated descriptors. The most common type of associative retrieval mechanism is based upon the use of a thesaurus to associate index or query terms with related terms. In traditional associative retrieval, these associations are crisp.

Fuzzy associative retrieval mechanisms obviously assume fuzzy associations. A fuzzy association between

two sets $X = \{x_1, \dots, x_m\}$ and $Y = \{y_1, \dots, y_n\}$ is formally defined as a fuzzy relation

$$f : X \times Y \rightarrow [0, 1]$$

where the value $f(x, y)$ represents the degree or strength of the association existing between the values $x \in X$ and $y \in Y$. In IR, different kinds of fuzzy associations can be derived depending on the semantics of the sets X and Y .

Fuzzy associative mechanisms employ fuzzy thesauri, fuzzy pseudothesauri, fuzzy ontologies, and fuzzy categorizations to serve three alternative, but compatible purposes: 1) to expand the set of index terms of documents with new terms; 2) to expand the search terms in the query with associated terms; and 3) to expand the set of the documents retrieved by a query with associated documents.

Fuzzy Thesauri

A thesaurus is an associative mechanism that can be used to improve both indexing and querying. It is well known that the development of thesauri is very costly, as it requires a large amount of human effort to construct and to maintain. In highly dynamic situations, i.e., volatile situations, terms are added and new meanings derived for old terms quite rapidly, so that the thesaurus needs frequent updates. For this reason, methods for automatic construction of thesauri have been proposed, named pseudothesauri, based on statistical criteria such as the terms' co-occurrences, i.e., the simultaneous appearance of pairs (or triplets, or larger subsets) of terms in the same documents.

In a thesaurus, the relations defined between terms are of different types. If the associated descriptor has a more general meaning than the entry term, the relation is classified as broader term (BT), while a narrower term (NT) is the inverse relation. Moreover, synonyms and near-synonyms are parts of another type of relationship associated by a related term (RT) connection.

The concept of a fuzzy thesaurus has been suggested,^[27,31,53,54] where the links between terms are weighted to indicate the relative strengths of these associations. Moreover, fuzzy pseudothesauri are generated when the weights of the links are automatically computed by considering document relationships rather than concept relationships.^[30,55]

The first work on fuzzy thesauri introduced the notion of fuzzy relations to represent associations between terms.^[54,56] Let us look at a formal definition of a fuzzy thesaurus.^[27,28] Consider T to be the set of index terms and C to be a set of concepts. Each term $t \in T$ corresponds to a fuzzy set of concepts $h(t)$:

$$h(t) = \{\langle c, t(c) \rangle \mid c \in C\}$$

in which $t(c)$ is the degree to which term t is related to concept c . A measure M is defined on all of the possible fuzzy sets of concepts, which satisfies:

$$\begin{aligned} M(\emptyset) &= 0 \\ M(C) &< \infty \\ M(A) &\leq M(B) \quad \text{if } A \subseteq B \end{aligned}$$

A typical example of M is the cardinality of a fuzzy set. The fuzzy RT relation is represented in a fuzzy thesaurus by the similarity relation between two index terms, t_1 and $t_2 \in T$ and is defined as

$$s(t_1, t_2) = M[h(t_1) \cap h(t_2)] / M[h(t_1) \cup h(t_2)]$$

This definition satisfies the following:

- if terms t_1 and t_2 are synonymous, i.e., $h(t_1) = h(t_2)$, then $s(t_1, t_2) = 1$;
- if t_1 and t_2 are not semantically related, i.e., $h(t_1) \cap h(t_2) = \emptyset$, then $s(t_1, t_2) = 0$;
- $s(t_2, t_1) = s(t_1, t_2)$ for all $t_1, t_2 \in T$; and
- if t_1 is more similar to term t_3 than to t_2 , then $s(t_1, t_3) > s(t_1, t_2)$.

The fuzzy NT relation, indicated as nt , which represents grades of inclusion of a narrower term t_1 in another (broader) term t_2 , is defined as:

$$nt(t_1, t_2) = M[h(t_1) \cap h(t_2)] / M[h(t_1)]$$

This definition satisfies the following:

- if term t_1 's concept(s) is completely included within term t_2 's concept(s), i.e., $h(t_1) \subseteq h(t_2)$, then
- $$nt(t_1, t_2) = 1;$$
- if t_1 and t_2 are not semantically related, i.e., $h(t_1) \cap h(t_2) = \emptyset$, then $nt(t_1, t_2) = 0$; and
 - if the inclusion of t_1 's concept(s) in t_2 's concept(s) is greater than the inclusion of t_1 's concept(s) in

$$t_3 \text{'s concept(s), then } nt(t_1, t_2) > nt(t_1, t_3)$$

By assuming M as the cardinality of a set, s and nt are given as:

$$\begin{aligned} s(t_1, t_2) &= \frac{\sum_{k=1}^M \min[t_1(c_k), t_2(c_k)]}{\sum_{k=1}^M \max[t_1(c_k), t_2(c_k)]} \\ nt(t_1, t_2) &= \frac{\sum_{k=1}^M \min[t_1(c_k), t_2(c_k)]}{\sum_{k=1}^M t_1(c_k)} \end{aligned}$$

A fuzzy pseudothesaurus can be defined by replacing the set C in the definition of $h(t)$ above with the set of

documents D , with the assumption that $h(t)$ is the fuzzy set of documents indexed by term t . This yields

$$h(t) = \{(d, t(d)) | d \in D\}$$

in which $t(d) = F(d, t)$ is the index term weight defined above. F can be either a binary value defining a crisp representation, or it can be a value in $[0, 1]$ to define a fuzzy representation of documents. The fuzzy RT and the fuzzy NT relations now are defined as:

$$\begin{aligned} s(t_1, t_2) &= \frac{\sum_{k=1}^M \min[F(t_1, d_k), F(t_2, d_k)]}{\sum_{k=1}^M \max[F(t_1, d_k), F(t_2, d_k)]} \\ nt(t_1, t_2) &= \frac{\sum_{k=1}^M \min[F(t_1, d_k), F(t_2, d_k)]}{\sum_{k=1}^M F(t_1, d_k)} \end{aligned}$$

Note that $s(t_1, t_2)$ and $nt(t_1, t_2)$ are dependent on the co-occurrences of terms t_1 and t_2 in the set of documents, D . The set of index terms of document d , i.e., $\{t \mid F(d, t) \neq 0 \text{ and } t \in T\}$, can be augmented by those terms t_A which have $s(t, t_A) > \alpha$ and/or $nt(t, t_A) > \beta$ for parameters α and $\beta \in [0, 1]$.

Suppose that in the definition of F we have the set T as a set of citations which are used to index documents, rather than a set of terms. In this case, a fuzzy association on citations can be defined through the fuzzy relations of s and/or nt . By using citations, a user may retrieve documents that cite a particular author or a particular reference. In addition, a keyword connection matrix has been proposed to represent similarities between keywords in order to reduce the difference between relationship values initially assigned using statistical information and a user's evaluation.^[57] A new method is also proposed in which keywords that are attached to a document and broader concepts are hierarchically organized, calculating the keyword relationships through the broader concepts.

Moreover, a thesaurus can be generated based on the max-star transitive closure for linguistic completion of a thesaurus generated initially by an expert linking terms.^[58] In addition, a probabilistic notion of term relationships can be employed by assuming that if one given term is a good discriminator between relevant and nonrelevant documents, then any term that is closely associated with that given term (i.e., statistically co-occurring) is likely to be a good discriminator, too.^[10] Note that this implies that thesauri are collection-dependent.

One can also expand on Salton's^[59] use of the $F(d, t)$ values. Salton^[60] infers term relationships from document section similarities. On the other hand, one can manipulate the $F(d, t)$ values in order to generate co-occurrence statistics to represent term linkage weights.^[61] Here, a synonym link is considered, defined as:

$$\mu_{\text{synonym}}(t_1, t_2) = \sum_{d \in D} [F(d, t_1) \leftrightarrow F(d, t_2)]$$

where $F(d, t_1) \leftrightarrow F(d, t_2) = \min[F(d, t_1) \rightarrow F(d, t_2), F(d, t_1) \leftarrow F(d, t_2)]$ and $F(d, t_1) \rightarrow F(d, t_2)$ can be defined in variety of ways. For instance, $F(d, t_1) \rightarrow F(d, t_2)$, the implication operator, can be defined as $[F(d, t_1)^c \vee F(d, t_2)]$, where $F(d, t_1)^c = 1 - F(d, t_1)$ is the complement of $F(d, t_1)$ and $\vee$ is the disjunctive (OR) operator defined as the max; or it can be defined as $\min(1, [1 - F(d, t_1) + F(d, t_2)])$. Here, a narrower term link (where term t_1 is narrower than term t_2 , so term t_2 is broader than term t_1), is defined as:

$$\mu_{\text{narrower}}(t_1, t_2) = \sum_{d \in D} [F(d, t_1) \leftrightarrow F(d, t_2)]$$

Note that fuzzy narrower relationships defined between fuzzy sets can help the purpose of identifying generalization and specialization of topics, while the fuzzy similarity relationship between fuzzy sets can be of aid to identify similar topics. Thus they serve to build a labeled graph of relationships between concepts, regarded as fuzzy sets of terms, in the specific domain of the collection.

Fuzzy Clustering for Documents

Clustering in IR is a method for partitioning D , a given set of documents, into groups using a measure of similarity (or distance) which is defined on every pairs of documents. Grouping like documents together is not a new phenomenon, especially for librarians. The similarity between documents in the same group should be large, while the similarity between documents in different groups should be small.

A common clustering method is based on the simultaneous occurrences of citations in pairs of documents. Documents are clustered using a measure defined on the space of the citations. Generated clusters can then be used as an index for IR, i.e., documents which belong to the same clusters as the documents directly indexed by the terms in the query are retrieved.

Similarity measures have been suggested empirically or heuristically, sometimes analogously to the similarity measures for documents matched against queries.^[33,38,62] When adopting a fuzzy set model, clustering can be formalized as a kind of fuzzy association. In this case, the fuzzy association is defined on the domain $D \times D$. By assuming $R(d)$ to be the fuzzy set of terms representing a document d with membership function values $d(t) = F(d, t)$ being the index term weights of term t in document d , the symmetric fuzzy relation s , as originally defined above, is taken to be the similarity measure for clustering documents:

$$\begin{aligned} s(d_1, d_2) &= \frac{\sum_{k=1}^M \min[d_1(t_k), d_2(t_k)]}{\sum_{k=1}^M \max[d_1(t_k), d_2(t_k)]} \\ &= \frac{\sum_{k=1}^M \min[F(t_k, d_1), F(t_k, d_2)]}{\sum_{k=1}^M \max[F(t_k, d_1), F(t_k, d_2)]} \end{aligned}$$

in which T is the set of index terms in the vocabulary and M is the number of index terms in T .

In fuzzy clustering, documents can belong to more than one cluster with varying degree of membership.^[63] Each document is assigned a membership value to each cluster. In a pure fuzzy clustering, a complete overlap of clusters is allowed. Modified fuzzy clustering, also called soft clustering, uses thresholding mechanisms to limit the number of documents belonging to each cluster. The main advantage of using modified fuzzy clustering is the fact that the degree of fuzziness is controlled. The use of fuzzy clustering in IR have several applications, that span from unsupervised categorization of documents into homogeneous overlapping topic categories, so as to offer users an overview of the contents of a collection or to organize the results of a search into labeled groups, thus allowing users to have an immediate view of what has been retrieved. With respect to crisp clustering, fuzzy clustering allows finding a document in several labeled groups, thus reflecting distinct interpretation of document's content.

FUZZY PERFORMANCE MEASURES

One problem with current criteria to measure the effectiveness of IRSs is the fact that Recall and Precision measures have been defined by assuming that relevance is a Boolean concept. In order to take into account the fact that IRSs rank the retrieved documents based on their RSVs that are interpreted either as a probabilities of relevance, similarity degrees of the documents to the query, or as degrees of relevance, Recall–Precision graphs are produced in which the values of precision are computed at standard levels of recall. Then the average of the precision values at different recall levels is computed to produce a single estimate.

Nevertheless, these measures do not evaluate the actual values of the RSVs associated with documents and do not take into account the fact that also users can consider relevance as a gradual concept. For this reason some authors have proposed some fuzzy measure of effectiveness. Buell and Kraft^[46] proposed the evaluation of fuzzy recall and fuzzy precision, defined as follows:

$$\text{Fuzzy precision} = \frac{\sum_d \min(e_d, u_d)}{\sum_d e_d},$$

$$\text{Fuzzy recall} = \frac{\sum_d \min(e_d, u_d)}{\sum_d u_d}$$

where u_d is the user's evaluation of the relevance of document d (u_d can be binary or defined in the interval $[0, 1]$) and e_d is the RSV of document d computer by the IRSs. These measures take into account the actual values of e_d and u_d , rather than the rank ordering based in descending order on e_d .

These measures can be particularly useful to evaluate the results of fuzzy clustering algorithms.

CONCLUSIONS

This entry reviews the main objectives and characteristics of the fuzzy modeling of the IR activity with respect to alternative approaches such as probabilistic IR and vector space IR. The focus of the fuzzy approaches is on modeling imprecision and vagueness of the information with respect to uncertainty. The fuzzy generalizations of the Boolean Retrieval model have been discussed by describing the fuzzy indexing of structured documents, the definition of flexible query languages subsuming the Boolean language, and the definition of fuzzy associations to expand either the indexes or the queries, or to generate fuzzy clusters of documents. Fuzzy similarity and fuzzy inclusion relationships between fuzzy sets have been introduced that can help to define more evolved fuzzy IR models performing "semantic" matching of documents and queries, which is the current trend of research in IR.

Abstract

Games and gaming are more visible and viable in libraries as computer, console, and tabletop games gain popularity as a form of leisure and recreation. Even though libraries have supported games in one form or another for many years, this type of collection is still controversial. Librarians with the guidance of professional groups, scholars, and educators are working together to show the value of games in all types of libraries. Games and gaming in public libraries are growing beyond simply providing space for their recreational use to include targeted programs to increase diversity. They are also being used to encourage collaboration and learning across all ages. Many public libraries host game programs, facilitate game play, and even encourage game creation. All types of games are now more readily recognized for their educational value in school classrooms and libraries. School librarians encourage the use of games to meet educational goals, life skills, and digital citizenship in the classroom. Academic libraries and archives are not only building game collections to aid in programming, retention, and research, but also creating archival and digital repositories to aid future scholars. Despite the technology and digital rights management difficulties inherent to video games, libraries recognize the historical and cultural value of games and the need for this type of collection. Librarians are not only developing ways to support leisure, research, and game preservation, but also the creation of games in and for libraries.

INTRODUCTION

Games and gaming in libraries is a hot topic at the present time for many librarians who wish to attract users to the library. Game collections and gaming as an activity mean different things to different people in the library and community at large. Librarians are working together to provide access to this type of collection as well as promote the positive influences of games in the library.

This entry will give a basic definition of what games are and why they belong in the library. It will also give brief descriptions of how games are being used in public, school, and academic libraries to enhance recreation, learning, and scholarly research. Lastly, an overview of how librarians are not only collecting games but also creating games to help entertain and educate their patrons. Librarians are creating organizations and harnessing the positive influence of this dynamic and evolving format.

DEFINITION OF A GAME

What is a game? The definition of a game changes context according to the situation in which it is used. Kevin Maroney defines games as a form of play that has structure and set goals. The structure can include sequence and timing of the action. These actions can be strictly

described in the rules or more flexible, such as those in a role-playing game where a player is limited by their specific attributes. Actions the players take in any game are to reach a set goal or objective and possibly win the game.^[1] Jesper Juul adds to this by including player effort and attachment as necessary elements of a game. A player invests effort to influence the outcome and, therefore, becomes attached to that outcome.^[2] This goes to show that games are not just physical objects with goals and structure but also an activity.^[3] Each iteration of gameplay can be different than the one before as the players and their knowledge, ability, and expertise change. Games must be played, and gameplay is different every time a game is played. This means games are ever changing and players must react and refine their play to be successful. Play is a valuable part of learning and video and tabletop games let us play regardless of age or infirmity. It allows users to practice behaviors and experiment without any real-life consequences.^[4] Gamers interact, collaborate, and engage with the game and each other as they seek to accomplish the game's goals.

Most library games fit this definition of a game. Library collections are most likely in the format of computer, console, and tabletop games. PC games or computer games are video games played on a personal computer. Video games can also be played on game consoles. These games are usually specific to a certain console type and model.

Consoles, unlike PCs, were designed just for the purpose of playing games, although that has been changing to include Internet access and other uses with the latest console models.^[5] Computer and console games are digital games that require hardware platforms to be playable. Tabletop games is an inclusive term that refers to games that can be played on a table's surface such as board games, card games, role-playing games, and dice to name a few. These games vary in their materials to include boards, pieces, dice, cards, paper, pencil, and role-playing guides, in book and digital form. These are just the predominant formats that a library might have in their collection. The world of games is very broad and varied.

GAMES IN THE LIBRARY

Gaming might appear to be a new type of activity in the library to many people; however, games have been in libraries, in one form or another, for the past 150 years.^[6] As both tabletop and video games have become mainstream and connected to other types of mass media, gaming in libraries has gained visibility. Over the last 40 years, gamers have grown up and had children that may also game. This has led to gaming being a more readily accepted leisure activity for all ages.

The Entertainment Software Association Industry Facts show that 59% of Americans play video games. This means that 183 million people play video games in America. It's not just kids playing these games. The average age of a gamer is 31.^[7] Why do people play video games? The author of *Reality is Broken*, Jane McGonigal, believes that games are fulfilling some of the needs that people are not getting from the real world. Engaging games teach and inspire gamers. Unable to find this type of fulfillment in their daily real-world life, people are turning to virtual worlds.^[8] One benefit of games is the ability to fight, die, and rise up to try another strategy that can accomplish the games' given goals. People are able to vanquish villains, be a hero that saves the world, or simply have a successful farm in their virtual life. Games give this type of success to the average person.

Beyond the use of games for leisure, librarians have a duty to consider collections that have cultural significance. Music, movies, books, and games are more intertwined now than at any time in the past. Barwick, Dearnley, and Muir note that games deserve a rightful place in libraries because they are an important part of the history of play. Games are a part of our cultural legacy.^[3] Although digital games are what usually come to mind when people think of a game collection, tabletop games have also had a resurgence in the last 10 years. Now tabletop games offer better design and deeper engagement while also being more accessible because of the Internet.^[9] Librarians are ignoring a significant part of modern cultural heritage if they do not consider tabletop and digital games worth collecting for their user's benefit.

This resurgence in tabletop games and the continued popularity of video games as a type of mass media led to the creation of an American Library Association (ALA) Member Interest Group focused on games and gaming in libraries in 2008. In 2012, this group became the ALA Games and Gaming Round Table (GameRT). The GameRT website (<http://www.ala.org/gamert/home>) lists their mission as offering librarians a professional forum for ideas, resources, and support. As a professional group, GameRT is able to provide a positive voice and create awareness of the value of games and gaming in libraries.

Do Games Belong in a Library?

There has always been conflict around the inclusion of games and other new media in libraries. The idea of supporting leisure materials, regardless of format, has been debated by librarians for at least 150 years. Hayes and Morris note that collections including leisure materials struggle to be accepted by librarians but are generally the reason that the public uses libraries. Librarians in the past were asked by social reformers to provide only materials that improve both the user and society through their leisure activities. Problems arise in the fact that no one can agree to just what type of material this is.^[10] Librarians today are still fighting this battle. Librarians in the process of establishing a new collection should keep in mind that almost every new type of library material was seen as a threat to literacy, even fiction novels.^[11]

Not only do librarians need to deal with ingrained ideas about librarianship and library collections, they must also deal with how today's popular media portrays gaming. News stories tend to focus on controversial games or the negative aspects of games, while ignoring the vast number of players who play without any issues arising.^[12] James Paul Gee articulates that the number of people who have killed others or aided them because of a book is vastly larger than those who have done so because of a game, movie, or television show.^[13] Focusing only on the negative aspects of any material or format will only lead to an empty library that no one wants to visit or support.

Despite naysayers, some librarians have responded to the public's demand and started game collections. These librarians realize that games are a part of our culture and, as such, should be collected for their users' benefit. Libraries have a duty to provide materials for their users to be informed citizens. Many might say games don't count, whereas Sandy Farmer explains that entire conversations take place in society today that revolve around the cultural references that occur in games.^[14] Providing access to these games allows users without home access to understand these references and participate in this part of culture. Library game collections still cause some controversy; however, the benefits of games and gaming are developing day by day. Game collections are merely another resource for the edification and leisure of library patrons.

Public Libraries and Gaming

Games and gaming fit the mission of many public libraries, which is to support the public's information and learning needs. Public libraries support these needs in many different ways. For example, The Mechanics' Institute Library of San Francisco has been supporting the public by hosting a chess club since 1854.^[6] Public libraries are not only playing chess but are expanding to include other types of games and gaming programs in their libraries. Public library game programs exist for all ages. John Pappas at The Primos Library in Secane, Philadelphia, began a Golden Gamers Group for gamers aged 65+. Board games provide these gamers with a social experience that is also interactive and engaging.^[15] Patrons at the Bainbridge Library in Bainbridge Island, Washington, get to solve a Murder Mystery, searching for clues throughout the library. Audrey Barbakoff initiated this type of game to help bring in a more diverse crowd and this program met its goal.^[16] Gaming programs can be developed to cater to an individual library's needs.

Who is gaming in public libraries? In a survey from 2007, when the question was asked very broadly to include hosting a chess club or allowing web-based games to be played on public computers, the results were that 77% of public libraries support gaming. Nearly half of these libraries hosted gaming programs. 90% of the formal programming used board games, with 45% of this group noting the games were traditional games such as chess. Almost a quarter of libraries with game collections included console games, and a much smaller group, 7%, included computer games. Card games, other than those considered traditional such as Bridge, were used 19% of the time, with role-playing games being used 4% of the time.^[17]

Some of these libraries support the in-house use of games as well as circulating them. Twenty percent of public libraries surveyed in 2007 circulated games, with board and card games being the most circulated types of games. These libraries also circulated computer games, puzzles, and console games.^[17] In 2008, the Houston Public Library started circulating video games, controllers, and consoles. They estimate the average cost to be about \$1 per library customer.^[14] These circulating collections give patrons a chance to try out new games when they would not be otherwise able to do so because of costs or availability.

Games and gaming are a natural fit for public libraries. Public libraries have shown that games are a valuable part of their collection as well as a great resource for event programming. Thoughtful use of a library game collection can encourage collaboration and communities through play.

Games in School Libraries

Like in public libraries, games have been a fixture in public schools for years. Nicholson notes in his article,

"Playing in the past: a history of games, Toys, and Puzzles in North American Libraries," that various other libraries and library associations have encouraged the use of games to facilitate learning. The use of games in libraries was included in a guide published by the ALA in 1920 because games stimulate an interest in reading. Another *School Library Journal* article in 1979 promoted developing learning games.^[17] The interest in using games and gaming for educational goals, like games themselves, is having a resurgence. This renewed interest is due to technology, new designer games, and recent changes in educational goals.

How are public schools using games? Scott Nicholson surveyed librarians to gather a census of gaming programs and practices in 2007. Of the 314 responses, 78 were school media libraries. Thirty percent of these school media libraries circulated games, with the majority, 19%, being board games. Nine percent circulated PC games and 3% circulated Nintendo, PlayStation, or Xbox console games. Web-based games were allowed in half of these school media libraries. Thirty-two percent of these libraries only allowed educational games, but 17% allowed recreational games during free periods. This survey also gathered data on the programs being offered in the school media libraries. Half of the programs were educational and half recreational. Problems with noise, space, and supervision were noted as being limitations for recreational school gaming programs.^[18]

As the survey shows, school libraries are using games, but not to their full potential. School librarians, with the right resources, can help educators meet educational goals with games and gaming. Brian Mayer and Christopher Harris are two educators who are actively involved in integrating tabletop games into the classroom curriculum in their school district. They believe that using games, especially the new Eurogames, require students to explore, learn, and act on what they have learned. They often must gather information from several sources to be successful.^[19] Many games can be aligned with the learning standards and outcomes while also allowing collaboration and cooperation among players. In classrooms, gameplay is often used as a reward; it can also function as a valuable part of the lesson. Games can be used, much like fiction is used in English classes, as a part of daily instruction to enhance learning and provide historical context.^[19]

In the article "Three different paths for tabletop gaming in school libraries," three school librarians detail how they are using games educationally as well as recreationally to benefit their students. The first school, a high school in the United Kingdom, took the path of starting an after school board game club called "Unplugged." This club offers a haven for students. It allows them the benefit of team building and socializing with their peers.^[20] Tabletop gaming clubs, for many librarians, is one of the easier ways to start a games and gaming collection because of the minimal costs and labor involved at the outset. A successful afterschool club confirms the benefits of

gaming to educators and school administrators. This small step can lead to the start of a library game collection and eventually to the successful integration of games into classroom learning.

The second path is to have students act out a game of the “Trials of Socrates,” based on the role-playing game series developed by Barnard College called “Reacting to the Past.” To be successful in this game, students must study the time period, read *The Iliad* and *The Odyssey*, and hone their debate skills. These students learn by role-playing a character. They immerse themselves in a role with a background, alliances, and goals. The teacher acts as the game master. This type of learning through role-playing has led to the students and teachers becoming more creative. After this success, some of the teachers wrote a role-playing scenario to teach about the “Salem Witch Trials.” This school also offers the students an opportunity to create their own games.^[20]

The third path is to build a comprehensive library collection that aligns with state and national learning standards to help teach students through play. Brian Mayer, the specialist who curates this collection, actively facilitates gameplay in the classroom. This allows him to grow the collection to align with learning standards and incorporate life skills, such as fine motor skills, social skills, and problem-solving.^[20] All three of these paths are beneficial to students; however, it requires buy-in from students and staff. The first step is always hardest and the same holds true for introducing games and gaming to an institution.

Information literacy can be developed using games. Digital citizenship, a form of information literacy for responsible participation in a networked society, is taught to students in schools using *Minecraft*. The virtual world, *MinecraftEdu*, was created in 2011 to help support learning. Students collaborate, communicate, and engage with each other in this world. Their virtual interactions inherently lead to virtual offenses and conflicts. This facilitated and monitored play allows these students to learn suitable online behaviors under the guidance of a teacher in an environment with minimal consequences.^[21]

There are still obstacles for game collections in schools. The value of a game for use in a curriculum is measured by its educational components. Many games produced for the education market are lacking in their ability to engage users. This is because the educational value of a game cannot be determined by the label but by what the player brings and takes away from the game. Mass market games and even independent games can be educational because many of these games incorporate good learning principles, such as strategic thinking and problem-solving.^[22] These games usually succeed where games designed with educational goals fail because they grab the buyer’s attention and keep it to stay profitable. Many popular games motivate the user by offering challenges that require learning and research to be an effective player. These games have communities and wikis

that discuss strategy, include statistical analysis of attributes for each class, expand on the lore or history of the game, and much more. Players are building up skills and literacies as they accomplish the game’s goals.^[23] Many games developed purely for the educational market are still falling short of their educational goal because they are skill and drill games. They are more palatable but often do not offer the user a chance to be a creative and innovative problem solver.^[24] This is not to say that games designed to be educational should be ignored; however, librarians should look at all genres of games to find suitable items for their school library collection.

The use of facilitated and guided play using games and gaming in schools is valuable for students as they move through a world of technological and social change. The benefit of play is that it gives students a chance to learn from their mistakes and improve on their strategies as they encounter their world, both real and virtual, without worldly consequences. School librarians are seeing success in their integration of games into learning. This will continue to grow as students, teachers, and administrators become more comfortable with this media.

Games in Academic Libraries

Games and gaming collections in academic libraries have a slower growth than in public and school libraries. It’s gaining momentum and acceptance as the need for research into games and their social impact grows. Academic libraries are starting to build collections to support research, programs that use games in their curriculum, as well as for student recreation and retention.

Do games belong in an academic library? The growth of games and gaming in society and as an industry has spurred several academic libraries to begin a collection to support its study and research. Laskowski and Ward note what issues need to be explored while building a video game collection in their paper, “Building next generation video game collections in academic libraries.” They include the following as the main issues to explore, determining what students, instructors, and researchers need for their work; purchasing the appropriate hardware to support the required formats, navigating the software and licensing issues related to video games, and providing appropriate library support.^[25] This type of collection development is dependent on the technology changes and evolution of video games and their platforms, whether PC or console. The amount of technology support in the library is important to the collection’s goals. Without the appropriate technology, a collection will not be usable. Sustainability of game’s accessibility and collection goals should be taken into account with all purchases and donations.^[26]

Technology, digital rights management, and computer security on college campuses are big concerns for a video game collection. The technology related to games, like other digital technology, is in constant flux, so new hardware, formats, and digital updates are always on the

horizon. Access to games is limited by digital rights management that the manufacturer includes and security networks on the campus or in the library. The viability of a digital game collection in a library is vulnerable to many factors out of their control. Despite these odds, academic libraries are building leisure and educational collections on their campuses.

Not only is the technology and accessibility of games changing, but the types of courses that might use games in the curriculum is changing fairly rapidly as well. Computer science programs with classes in game design will probably benefit from use of a collection; however, programs that use games exist in other academic departments as well, such as art and design, music composition programs, communications, and mass media. As the research in games and the culture that surrounds it changes, the library collection needs to change as well.

Tabletop games should not be overlooked when building an academic game collection. These games are generally much easier to collect than video games. However, they do bring their own set of issues as do other nonbook formats. A tabletop collection is a great way to introduce games and gaming into the library without the technology and digital rights management issues of video games. If the library does not have sufficient technology or administrative support for a video game collection, a successful tabletop collection can garner positive attention and eventually draw support for a video game collection. Small, successful steps are better than big fails for a gaming collection.

For most academic libraries, a gaming collection is much more than just a research resource; it can also be used for library programming and outreach. Library outreach seeks to introduce students to library services and help with retention—especially among first-year students—by building a sense of community. Library space is not limited to particular departments, so students from diverse programs can use it to meet and work together. Libraries with gaming collections and programming are particularly well suited for community building. Most gameplay includes social elements either through cooperative and collaborative play or discussion around single-player games. Gaming is like electricity for some college students today. It has always been a part of their lives even if they didn't actively take part in gaming while growing up.^[27] With a little help from residence life coordinators, campus student groups, and social media, librarians can create a physical, social space for gaming in the library. The space alone may not help with retention, but it provides a level environment for interactions between faculty and students. These informal interactions can nurture a sense of belonging and self-worth.^[28] All of these feelings are integral to building community and ultimately increasing retention. An enthusiastic librarian or staff member that encourages play can easily accomplish this kind of fun, safe space.

Gaming, teaching, technology, and research are rapidly evolving, and there is much to do to support research

related to games. Academic libraries have an opportunity to move beyond collection building and into actively participating and collaborating in this interdisciplinary field.^[25]

Digital Preservation

Another aspect of games in libraries is the preservation and collection of digital data related to video games. Many academic libraries have digital repositories that include collections of digital objects. The digital objects include audio, visual, and text items. These repositories are capturing items from the past as well as current projects to aid researchers. The Game Preservation Special Interest Group of the International Game Developers Association has a white paper, "Before it's too late: a digital game preservation white paper," addressing the need to preserve electronic games.^[29]

Gaming enthusiasts with the technical expertise to convert games have emulated older games as a form of preservation, but with no regard for the rights of the creator. One of the largest old game collections is hosted on the Internet Archive. Part of the Internet Archives goal is to be "a searchable memory of society, and not just for scholars this time, but everyone".^[30] This has led them to provide access to classic arcade, console, and computer games on their software website at <https://archive.org/details/software>. These games are emulated to work in an Internet browser. Although the Internet Archive does not own the rights to these games, the Electronic Frontier Foundation is working to make it legal for older abandoned games to be modified by fans to remain playable.^[31]

Academic Libraries have their part to play in the preservation of games. Professional preservationists in libraries and museums are beginning to see the need to gather games and gaming data in their local repositories to aid in the preservation of gaming culture and history.^[3] Librarians can aid in the preservation of games by encouraging scholars and students to add copies of their digital game data to a university repository for preservation and research purposes.

Creating Games in Libraries

A number of librarians have created games for use by library patrons. There are two main reasons librarians will create a game: for outreach purposes and for instruction. Outreach games, such as murder mysteries or scavenger hunts, can help students and library patrons become comfortable with the library and hopefully cause them to visit the library more often in the future.

Public libraries hold outreach events, such as murder mysteries for adults or literature-themed events, like Hunger Games for teens. These events are fun in nature and used to help promote the library as a community place where community events can be held.^[32] The Daring Librarian shares an example of having students complete a QR Codes Quest (or scavenger hunt) to help them become familiar with library services at the school library.^[33]

Academic libraries can hold scavenger hunts as a fun way to help first-year students learn about the library during an orientation period. For example, the University of South Carolina Upstate invited first-year students to complete a photo scavenger hunt using the social media site of their choice and tagging the library in their photos.^[34] This is one of the promoted events during their orientation week. Students seem to enjoy taking selfies or photos of their new friends throughout the library. Some academic libraries make use of the murder mystery theme. The University of North Carolina Chapel Hill held a Clue event night at their special library to help students become comfortable being in the library.^[35] With Clue, a number of librarians helped out as different characters and provided participants with hints if they asked the right questions. Additionally, students looked in different parts of the library for additional hints.

These outreach events can take time to prepare, but are usually successful with patrons. There are websites where murder mysteries can be purchased for use in libraries, but librarians can design their own murder mysteries from scratch. Lycoming College held a Harry Potter-themed night for students with activities and games designed around the books for a number of years and this was quite successful with the students.^[36] This event was planned with the assistance of a number of librarians and faculty across campus. Assistants played different Harry Potter characters, as well as helping come up with games and activities.

One final type of outreach game that can be held in the library are large-scale, live-action games, such as *Capture the Flag* or *Humans versus Zombies*. These are events held inside libraries, often after the library is regularly closed, when large numbers of students can participate and have physical activities, such as using nerf guns to “kill” the zombies.^[37] At large universities, these types of large-scale events can bring hundreds of students to the library.

Instruction is an important part of academic librarianship in addition to school librarianship. Quite a few librarians started creating their own games with instructional goals. While the outreach games and events have an instructional component, the major purpose of these events is having fun in the library. There are a number of ways to create games for instructional purposes: the easiest being a board game and the most advanced being a digital game or web application.

The University of South Carolina uses a board game as an exit activity. After an instruction session, the game is played for a quick review of the material covered during class.^[38] The librarians used a map of the library that existed and added some numbers at key locations of the library. Students then answered questions about each location on the board. The students who correctly answer questions at the seven locations can leave first.

This is a quick and easy way to use games for instructional purposes. Board games are useable in any type of library and do not have to be complicated to create. Similar to board games, gamification can be used during

library sessions. Gamification is essentially using game elements to make things more fun and engaging. For example, Kahoot! is a recent quiz tool that creates multiple-choice questions to give students a gamified review of material. The game elements of Kahoot! include a timer, sound effects, images, and score-keeping (<https://getkahoot.com/>). More gamification tools will likely become available in the not-too-distant future.

One of the best and most used digital games created by a librarian is *Goblin Threat* by Mary J. Snyder Broussard at Lycoming College (<http://www.lycoming.edu/library/instruction/tutorials/plagiarismGame.aspx>). Mary allowed a number of librarians to use her game in their classes to help students avoid plagiarism. When playing *Goblin Threat*, students must answer questions about plagiarism correctly to make the goblins disappear and save the university. The librarians at the University of South Carolina Upstate used this game as a fun final activity for students during their plagiarism prevention workshops and students often listed this as their favorite activity.

The University of South Carolina Upstate has created an Agoge Game based on the journey of becoming a Spartan to fit the university’s mascot of Sparty, the Spartan (<http://agoge.uscupstate.edu/agoge/agogegame.html>). This game is based on *Goblin Threat* in its layout with multiple levels, answering questions correctly to advance, and a score. Music and images are included to create a more game-like atmosphere. Throughout the game, the warrior gains more armor and weapons after completing each level until they are a Spartan. This game was geared toward transfer students to test their information literacy skills. As an instructional tool, the game has embedded videos and screenshots of various library tools to help students who wish to learn more about the library.

The Game Making Interest Group within the Library and Information Technology Association of the ALA has a wiki that contains a wealth of game-making information (<http://gamemakinginterestgroup.wikispaces.com>). There are suggestions for incorporating games into instruction, as well as game creation best practices. A number of library game examples are included with links to more information and suggested readings (including books and articles about games in libraries and creating games). *Games in Libraries: Essays on Using Play to Connect and Instruct*, edited by Breanne A. Kirsch, provides more information about a number of the games discussed in this entry and suggestions on creating a library game.

CONCLUSION

Games and gaming in all types of libraries are evolving along with the gaming market and its consumers. Technology development will undoubtedly challenge libraries while educational changes will provide guidance. Librarians show that games, like any other media, have a

recognizable cultural influence and deserve a space in libraries as a beneficial collection to students, scholars, and the community.

ACKNOWLEDGMENT

The authors would like to acknowledge Dr. Scott Nicholson and Mary J. Snyder Broussard for all of their scholarship and guidance related to games and gaming in libraries.

Genealogical Literature and Its Users

Mavis B. Molto

Utah State University, Logan, Utah, U.S.A.

Abstract

Genealogical literature is the body of writings on genealogy, which is the study of ancestry and descent. This entry describes the history of genealogy, the users of genealogical literature, and the procedures and resources used in genealogical research. The steps in genealogical research consist broadly of a preliminary survey to identify what is already known about one's ancestors, using compiled sources, and then verifying and extending what is known, using original sources. A discussion of both compiled and original sources, along with reference tools and periodical, news, and networking sources, is included. Tables are presented outlining the major resources available in each of these areas, including resources for specific countries. Both print and online resources are identified.

INTRODUCTION

Definitions

Genealogical literature is the body of writings on genealogy, which in turn is the study of ancestry and descent. The term "genealogy" is sometimes used interchangeably with "family history." Powell explains the difference as follows:

"Genealogy, the study of ancestry and descent, refers more to the actual search for ancestors, while family history, the narrative of the events in your ancestors' lives, denotes the telling of your family's story. Family history is genealogy come alive."^[1]

This entry will focus on the literature and resources that are used to identify one's ancestors (i.e., names, and dates and places of birth, death, and marriage), though some of the resources discussed may also include the additional information one may want to know in writing a detailed family history.

Interest in Genealogy and Expansion of the Literature

Genealogy is the second most popular hobby in the United States, after gardening, according to an ABC News report.^[2] Polls show a steadily increasing interest among Americans in tracing their family history, with 60% "somewhat interested" in 2000 and 73% "interested" in 2005.^[3] A study commissioned by Ancestry.com in 2014 found "Over the past decade, online family history research has grown in the United States by 14 times, with two-thirds (63%) of respondents in a recent study reporting that family history has become more important than ever."^[4]

The increasing interest in genealogy is also evident in the growing number of theses and dissertations being written on various aspects of the genealogical literature and its users, with several examples discussed later.

Crandall, in the foreword to *Printed Sources*, describes the growing literature that is now available for genealogical research due to the increasing interest in genealogy:

"Genealogists are now much more numerous and genealogy much more popular than at any time in our national history. As this interest has proceeded, many authors and compilers have added immensely to the fast-growing multitude of printed sources for every kind of genealogy—compiled family or local histories, multi-ancestor works, new periodicals, guidebooks, printed source records, bibliographies, indexes, and reference works."^[5]

Meyerink adds the following concerning the genealogical literature:

"... [There] has been an explosion of printed genealogical sources. Every day several new books are published by and for genealogists; some major genealogical publishers release three or more new books and reprints *every week*."^[6]

He notes further:

"Although research methodology does not change rapidly, and original records are much the same as they were twenty or more years ago, there have been many changes in printed sources. In 1975 there were very few census indexes. The limited number of transcribed records meant limited access for the research. There were no computer programs or databases for family historians. Bibliographies and other research tools were fewer and much older than they are today."^[6]

Overview

This entry consists of a description of the history of genealogy, the users of genealogical literature, and the procedures and resources used in genealogical research. A discussion of both compiled and original sources, along with reference tools and periodical, news, and networking sources, follows.

HISTORY

Antiquity (to 1500)

A short history of genealogy is found in an article by Potter-Phillips, describing the keeping of genealogies in various ages, starting with Biblical times. References to genealogies are found in both the Old and New Testaments. The ancient Greeks, Assyrians, Egyptians, and Chinese also kept genealogies. Genealogies have been kept by many native peoples, including African clans, Maori and Inca peoples, and the North American Indians. During the Middle Ages in Europe, proving one's descent was required to claim the privileges of the nobility and gentry.^[7]

Beginning of Record Keeping and Modern Interest (1500s to Mid-1800s)

The ancient genealogies were frequently fragmentary and unreliable. In modern times, laws have been established in various countries requiring that records be kept of birth, marriage, and death, which in turn provides the documentation needed to construct accurate genealogies.^[7] However, even through the nineteenth century there were errors and lack of proof in genealogies because records were difficult to locate and examine.^[8]

The following are some important events in the development of record keeping in the United States and Europe:

- 1538—In Britain, an edict from King Henry VIII required that ministers keep records of christenings, baptisms, marriages, and burials.
- Mid-1500s—The lands that later became Germany began keeping records similar to the British records, and the Scandinavian countries followed.
- 1630s—In the American colonies, civil records were required in the General Assembly of Virginia in 1632 and in the Massachusetts Bay Colony in 1639.
- 1837—Civil registration began in Britain.^[7]

The first known genealogy in the United States was prepared in 1698: Pedigree of the Byrd family (at the Virginia Historical Society in Richmond).^[9] Genealogy, however, has not always been popular in the United States, due to the societies from which the early colonizers came. Traditions of inheritance and caste had denied them opportunities in achieving success, thus they often wanted to forget their heritage. Also, the early pioneers did not have the time required to do the research to identify their ancestors.^[8]

Rise of Organized Genealogical Endeavors (Mid-1800s to Early 1900s)

Bockstruck proposes that the beginning of genealogical research and publication in the United States occurred in the 1840s,^[9] with Bidlack noting that the publication of

genealogical source materials did not begin until after the Civil War.^[8] Wood describes the period 1848–1921 as a boom for genealogy.^[10]

Important developments occurred in the mid- to late 1800s with regard to county histories and historical associations. The first county history in America was published in 1848, for the County of Westchester (New York). In 1876, a Joint Resolution of Congress recommended that each county prepare a historical sketch to present on the centennial anniversary of the nation's independence, with copies to be filed in the county clerk's office and the office of the Librarian of Congress.^[9] In the latter half of the nineteenth century, historical associations were established in towns, counties, and states, and provided help in recording and preserving the local history.^[8] Key events regarding the historical associations include

- 1845—New England Historic Genealogical Society was founded,^[9] first genealogical society in the world.^[7]
- 1876—American Centennial stimulated the formation of patriotic societies and interest in looking back.^[8]
- 1876—Sons of the Revolution was organized in New York, first patriotic organization in America.^[9]
- 1903—National Genealogical Society was founded, in Washington, District of Columbia.^[9]

Scientific Genealogy and Growing Interest (Early 1900s–1969)

Mills reviews the history of genealogy, with a focus on the development of standards and scholarship. She describes various movements in genealogical scholarship and the emergence of “scientific” genealogy in the 1930s. The school of “scientific” genealogists was led by Donald Lines Jacobus (1887–1970), the father of American genealogy.^[11] Jacobus was the first American to make his living as a genealogist, for which he gained entry to *Who's Who in America* for his accomplishments.^[8] He established standards of genealogical scholarship^[11] and published important genealogical guides and reference materials, including

- 1930—*Genealogy as Pastime and Profession*, the first real guide for the beginner in family history^[8]
- 1933—*Is genealogy an exact science?*^[12]
- 1932–1953—*Index to Genealogical Periodicals*^[9]

Wood notes that prior to the 1970s organized genealogical research in North America tended to be a pastime for the white Euro-North American upper classes.^[10] Both of the world wars, however, promoted an interest in genealogy among Americans, as soldiers found themselves in the lands of their ancestors.^[8] After 1945, with the growing interest in genealogy, there was an increase in the number of hereditary societies^[9] and an increase in genealogical

source materials. Bidlack attributes the latter to the large number of people involved, along with the impact of technology, including offset printing, microfilm, copying machines, and, later, computers.^[8]

Wood describes the 1950s as the beginning of modern genealogy.^[10] Mills notes the establishment of several important organizations, beginning in 1940, which fostered the growth of standards and scholarship in the United States:^[11]

- 1940—American Society of Genealogists, recognized as the field's scholastic honor society
- 1950—National Institute for Genealogical Research, based at the National Archives
- 1964—Samford University's Institute of Genealogy and Historical Research
- 1964—Board for Certification of Genealogists, created in Washington, District of Columbia, to establish standards and a register of qualified genealogists^[8]

Genealogical Research Comes of Age (1969–1980s)

In 1969, the World Conference on Records, sponsored by the Church of Jesus Christ of Latter-day Saints (LDS Church), was held. This event promoted scholarship in genealogical research, as did the succeeding conference in 1980.^[8] Filby, Kaminkow, and others published important reference works during this period, including

- 1970—*American and British Genealogy and Heraldry*, by P. William Filby (ALA)^[9]
- 1972—*Genealogies in the Library of Congress: A Bibliography*, edited by Marion J. Kaminkow (Magna Carta Book Co.)^[9]

In 1976, Alex Haley's book, *Roots: The Saga of an American Family*, was published and the popular television drama based on it began in 1977. Both stimulated interest in family history among a wider range of people, including minority groups.^[10] Patrons at genealogical and historical libraries doubled and tripled during the 1970s,^[8] including a 70% increase in use, in 1979, by genealogists at the National Archives and Records Administration.^[10]

Prior to 1980, the image of genealogy was poor, since genealogy was often performed for exclusion and the promotion of social ambition. Changes in the 1980s prompted American historian Samuel P. Hays to maintain that a "new genealogy" had emerged. Wood, in a thesis, examines the "new genealogy" over the period 1969–2004, noting "a significant shift in the characteristics of genealogical research in North America at least" during this period. Characteristics of the new genealogy included:^[10]

- More focus on archival research by those outside the social elites.

Interest in family history among a wider range of people.

Interest in more than illustrious or elite ancestral ties.

Interest in the historical context in which the family lived.

Flourishing of genealogical societies, publications, and codes of ethics.

Adoption of the Internet as a major research tool.

Improvement in the relationship between archivists and genealogists.

Genealogical research becoming the basis of media reports, plays, and books.

Genealogical research becoming an important aspect of medical care.

The Internet and Digitization (1990s–2000s)

The Internet and digitization have played major roles in developments pertaining to genealogy in the 1990s and on. Crandall notes that: "...CD-ROMs and the Internet ... will not so much replace the older literature as place it in a new format."^[5] Following are some of the genealogical websites established during the 1990s to early 2000s (see Table 1 for further details):

- 1993—RootsWeb
- 1996—Cyndi's List
- 1996—WorldGenWeb Project
- 1997—Ancestry.com
- 1999—FamilySearch
- 1999—Heritage Quest
- 2003—Linkpendium (beta version)
- 2005—MyHeritage

Over 40 million hits were received at the FamilySearch website on its first day of operation in 1999.^[10] As the popularity of the genealogical websites has grown, so has the interest in building family trees online and in sharing the trees within families and communities. Sites that provide these capabilities include Ancestry.com, MyHeritage, and FamilySearch (see Table 1).

As the genealogical websites have evolved, so have efforts to digitize resources. Digitization, the process of converting data or an image to digital form,^[13] is making possible the display of genealogical records on the Internet. Partnerships have been developed with genealogical providers to digitize extensive collections of genealogical materials. Several recent digitization projects are described below.

FamilySearch, a major player in the digitization efforts, announced partnerships in early 2014 with several commercial providers. Agreements were reached with Ancestry.com, Findmypast, and MyHeritage. The partnerships are seen as a way to accelerate digitization and to deal with the staggering amount of material needing digitization, as noted in the following:^[14]

Table 1 General resources

Category	Title	Content and URL (\$ = fee-based)
Directories— Intl.	Cyndi's List	http://www.cyndislist.com —Search by (1) category (place or topic), (2) keyword —Original directory of genealogical links —Over 300,000 links

U.K., U.S., Pacific	FindMyPast	\$ http://www.findmypast.com —Over 2 billion census, church, migration, military, and vital records —User-created family trees —How-to articles
U.S. emphasis	Heritage Quest Online	\$ http://www.heritagequestonline.com —Genealogical information for America since the late 1700s —U.S. census images (1790–1940) —Family history books —Periodical Source Index (PERSI) —Revolutionary War records —U.S. Congressional Serial Set (from 1789) —American State Papers

“Notwithstanding the astounding success of the FamilySearch indexing program and the tireless dedication of hundreds of thousands of volunteers, it will still take many generations to index and publish just the records contained in FamilySearch’s Granite Mountain Records Vault. This estimate does not account for the more than 35 million new images of records that are digitized each month—and that rate is increasing.”^[14]

Another significant partnership, between FamilySearch International and GenealogyBank, was announced on October 1, 2014. The two groups plan to make over a billion records from historical obituaries searchable online. This initiative has been described as the largest online U.S. historical record access initiative yet.^[15]

Many important U.S. records are being digitized through partnerships developed by the National Archives and Records Administration (NARA) with Ancestry, Fold3, and FamilySearch. The partners are digitizing selected NARA microfilm and original records and making the records available on their websites, with free searching allowed on some or all of the index terms. Free access to the records is available in the NARA Research Rooms and regional archives and Presidential libraries.^[16]

USERS OF GENEALOGICAL LITERATURE

Interest in Genealogy

Genealogical researchers have various reasons for their interest in genealogy. In earlier periods of time, the motivation for creating genealogies had to do with proving one’s descent so as to claim special privileges or social recognition. In more recent times, some have done genealogical research because of an interest in history. Others have sought meaning in their lives by developing ties with those in the past and present. Genealogical research is also performed to identify missing heirs of estates and to learn about hereditary diseases.

Still others have religious reasons for identifying their ancestors. The following explanation of LDS beliefs is found on the FamilySearch Wiki: “Members of the Church [of Jesus Christ of Latter-day Saints] believe that the family can continue beyond the grave. . . . Members of the church also believe that their deceased ancestors can receive this blessing of being eternally united with their families. This can be accomplished when Church members make covenants in temples in behalf of their ancestors, who may accept these covenants in the spirit world if they so choose.”^[17]

Studies of User Behavior and Needs

Most previous studies of genealogical users, in the library and information science and archival literature, have focused on managerial issues rather than the information needs and behavior of the users. A growing number of studies and

dissertations are now focusing on the information-seeking behavior of genealogists. Several studies are discussed here, with the findings summarized in the following five areas: 1) goals in genealogical research; 2) how genealogists search; 3) how genealogists learn; 4) how genealogists manage information; and 5) unmet needs of genealogists.

Goals in genealogical research: Yakel found no clear end goal in the genealogist’s search for information.^[18] “The ultimate need is not for a fact or date, but to create a longer narrative, connect with others in the past and present, and find coherence in one’s own life.” Self-identification and self-discovery are thus important dimensions of genealogical research.^[18] Yakel and Torres found, further, that genealogists as seekers of meaning are “less invested in proving the truth of stories and records, but more in uncovering coherent narratives.”^[19]

Antcliff Tucker, in a related dissertation, investigated whether people use family history to explore and articulate a sense of cultural identity. It was verified that family history research develops a sense of cultural identity, through discovery of one’s particular genealogy and through connecting with ancestral places and with a cultural group. Certain of the findings coincided with two of Yakel’s findings, namely, 1) “participants need to know their ancestors beyond a list of names and dates” and 2) “participants need to find and understand their ancestors’ stories.”^[20]

How genealogists search: Duff and Johnson identified three stages that are followed in genealogical research. In the first stage, genealogists gather names of their family members. In the second stage, they collect further details about the individuals. In these two stages, genealogists search by name and place, consult specific record forms for particular time periods, and search maps and gazetteers for names of localities in their area of research. The third and final stage involves finding out about the society and time period in which their ancestors lived.^[21]

Darby and Clough also looked at the research process used by genealogists and family historians, but with a different focus. A model was developed to describe the stages of activity carried out during a person’s lifelong family history research. The authors provide a multiphase view of the research process, showing “(1) the different research phases themselves; (b) the inter-relationship between phases; (c) distinct phase-specific behaviours; and (d) phase-specific resource preferences.”^[22]

Lucas, finally, in a dissertation focused more narrowly on how genealogists resolve problems, identified two distinct processes that are used. The two steps consist of 1) the location and selection of sources and 2) an information selection process for finding information in the sources. Once a problem is solved, new problems are identified and researched in an iterative process.^[23]

How genealogists learn: Duff and Johnson found that genealogists learn from one another. They tend to rely on their own expertise but when help is needed they consult most frequently with colleagues. A strong network exists

among genealogists, through associations developed in taking courses and attending genealogical society meetings and through newsletters.^[21] Fulton, in a related study of amateur genealogists researching their Irish ancestry, confirmed the importance of networking. Fulton found that networking and information sharing among fellow genealogists is an important means for advancing one's research.^[24] Yakel adds that genealogists and family historians turn to genealogical organizations for "education, celebration, and support." They also use Internet resources, such as online databases, chat rooms, LISTSERVs, and sites providing contact information for libraries and archives.^[18]

How genealogists manage information: The way genealogists and family historians manage information, according to a study by Yakel, is tied to how they conceptualize their role. Three roles were identified: narrators (telling a story), archivists (creating an archive of the research findings), and navigators (creating pedigree charts). The organizational devices used include genealogical software, notebooks, loose-leaf binders, and narratives.^[18]

Unmet needs of genealogists: Archives are organized by provenance or creator, but genealogists usually seek information concerning specific people. Duff and Johnson found that while expert genealogists have learned to use the provenance-based finding aids, the finding aids are a challenge for novice genealogists. Time constraints are also an issue for genealogists using archives. Professionals work on an hourly basis and need to find efficient ways to retrieve information in the archives. Nonprofessionals have concerns about the limited hours of service, especially in the evenings and on weekends.^[21]

USE OF LIBRARY CATALOGS AND CLASSIFICATION

Library catalogs and classification systems are important tools in providing access to the genealogical literature. Several studies and projects describe the problems and needs of genealogists in the use of the library catalog, and subject and classification systems. Though some of the studies were done prior to the implementation of the online library catalog, the findings remain relevant since many of the cataloging rules are still the same. The findings are described here.

Problems genealogists have with the library catalog: Users of genealogical libraries have been studied to identify the problems they have with the library catalog. The problems that occurred with the highest frequency at the Genealogical Library (Utah), in a study by Dilts, concerned 1) call numbers, 2) indirect locality entries in the catalog, 3) subject headings; and 4) filing rules. It was found, further, that these problems were often related to 1) patron inexperience with the Library (or catalog system), 2) the patron's use of incorrect or incomplete data, and 3) poor or inadequate cataloging.^[25]

Bibliographic elements of most use to genealogists: In another study, by Johnson, patrons at the Genealogical Library (Utah) identified the following bibliographic elements as needed or helpful, each having a combined percentage of 90% or more: title, author, illustrations, content notes, bibliographic references, index notes, and locality tracings. It was concluded that the existing catalog should be replaced with an abbreviated short entry catalog, since most patrons did not understand the more detailed catalog entries.^[26]

Analytic entry needs of genealogists: Sowers describes a project that identified how users approached research at the Kansas State Library. It was found they were often looking for specific information on individuals, events, institutions, etc. Subject access in the library catalog, however, was very broad. Following an experiment to create analytic entries in the catalog, for articles from the journal *Kansas History*, there was an immediate increase in the use of the articles and in interlibrary loan requests for the articles. The analytic entries provided access to the specific information the users were seeking.^[27]

Subject access needs of genealogists: Genealogists often seek information on the county level. To meet this need, the Rowan Public Library (North Carolina) added county-level headings, along with relevant subdivisions, to the library catalog, for example: "Wilkes County (N.C.)—Marriage records." These headings complemented the authorized LCSH headings, for example: "Marriage records—North Carolina—Wilkes County."^[28] With both kinds of headings in the catalog, access for the users was greatly improved.

Classification needs of genealogists: Genealogists have a need to browse library shelves by geographic area. The Rowan Public Library (North Carolina) designed a new classification for the History Room collection to accommodate this need, with materials arranged by geographic area and then by subject content, for example: KS KIN .34 [Kansas, Kingman County, marriage records]. In interviews, following the change, users said they liked the ease of use of the new system and being able to find materials for a county grouped together.^[28]

PROCEDURES IN GENEALOGICAL RESEARCH

Genealogical research is performed to identify and learn about one's ancestors. Some researchers are satisfied with creating only a pedigree chart, showing their line of descent, with names, dates, and places of their ancestors' births, deaths, and marriages. Other researchers want to learn more, including information about their ancestors' occupations, education, moves, and religious beliefs. In this entry, the focus will be on the steps needed to identify the basic details about one's ancestors, relating to birth, death, and marriage.

Steps in Research

An introduction to genealogical and family history research is found on the FamilySearch Wiki, in a document entitled: *A Guide to Research*. The document describes five steps in the research process:

- Step 1: Identify what you know about your family
- Step 2: Decide what you want to learn about your family
- Step 3: Select records to search
- Step 4: Obtain and search the record
- Step 5: Use the information^[29]

Step 1 in the research process consists of identifying what one already knows about one's ancestors, including information obtained from other family members. In gathering information, it is useful to contact both close and more distant family members and relatives. The objective is to learn about any research they have done and any family histories or genealogies they may have.

As one identifies names, dates, and places for one's ancestors, the information can be recorded on pedigree charts and family group records. A pedigree chart is "A chart that shows an individual's direct ancestors, [including] parents, grandparents, great-grandparents, and so forth. A pedigree chart may contain birth, marriage, and death information."^[30] A family group record is "A printed form that lists a family, parents and children, and gives information about dates and places of birth, marriage, and death."^[30] For each pair of ancestors one identifies (e.g., a grandfather and a grandmother), one would complete a family group record, with information about the husband and wife and their children. Both the pedigree charts and the family group records can be printed from the FamilySearch website.

Step 2 consists of choosing one ancestor about whom one wants to know more. One normally starts with the generation closest to oneself and then works back. In step 3, one selects the resources one will search, including both compiled and original records (discussed later). In step 4, one obtains the records and searches them. Step 5, finally, consists of evaluating and using the information found, copying any new information to one's pedigree and family groups records, organizing newly found records, and sharing the information with others.

This entry will focus on step 3, selecting records to search, since this is the step that is concerned most directly with the genealogical literature and in particular with the resources one must use to identify one's ancestors. In determining which records to search, one usually proceeds as follows:

- First, use compiled records to identify research already done on a given individual or family.

Second, use original records to locate new information about the individual or family.

As needed, use reference tools (background and finding aids) to assist in the two foregoing steps.

Classification and Evaluation of Genealogical Literature

The genealogical literature can be classified according to the types of resources used in the research process. Meyerink describes a classification that places genealogical resources into two broad classes:

1. "*Research sources* are those books and records which actually provide data that a researcher needs to solve a problem at hand. For family historians, these are the genealogical records which provide family data for charts and family group records."^[6]
2. "*Reference tools* provide auxiliary information to help researchers find the right research sources. Reference tools include bibliographies, indexes, instructional material, and other reference aids."^[6]

Research sources can, further, be subdivided into the following two classes:

1. "Original records are those sources that contain the first recording of an event...; they are generally recorded near the time of the event by someone who was present and associated with the event."^[6]
2. "Compiled records are those records that provide actual genealogical information whose content is derived from the research and evaluation of original records and/or other persons' research."^[6]

Reference tools, in turn, can also be subdivided into two classes:

1. "Background information helps researchers understand the settings in which records were created..."^[6]
2. "Finding aids indicate where specific information can be found..."^[6]

The foregoing subclassification of research sources contrasts with the more traditional view of primary versus secondary sources. Meyerink proposes that the information in the sources should be classified as primary or secondary, while the sources themselves should be classified as original or compiled, as explained here:

"The traditional definition of a 'primary source' has been that it is a record created at the time of the event by someone associated with the event. For example, a death record is usually considered to be a primary source because it is created at the time of the event by someone associated with the event, such as the attending physician or a close relative. However, only *some* of the information

in a death record is primary in nature. . . . Thus, on a death certificate, the death date and cause of death are primary information, but the dead person's birth date or parents' names are *not* primary information. Such information, which significantly predates the event being recorded, is secondary information. . . .^[6]

In conducting genealogical research, it is important to evaluate the information one finds, including a determination of whether the information is primary or secondary, as noted above. Other areas needing evaluation include relevance, origin of the information, nature of the record, format of the record, directness of the evidence, consistency and clarity of the facts, and likelihood of the event(s).^[6] Further guidance on evaluating information may be found in the how-to resources and guides listed in Table 4.

GENEALOGICAL RESOURCES

The genealogical literature will be discussed in further detail here, within the structure described earlier. Research sources will be described first, including compiled sources and original sources, followed by a discussion of reference tools. Some reference tools (e.g., indexes) will be discussed in conjunction with the original or compiled sources with which they are used. Resources that consist of a combination of original, compiled, and reference resources will be considered in the section that seems most pertinent. Periodical, news, and networking sources will be discussed separately, since these sources often contain a combination of resource types.

Tables have been prepared corresponding with the areas noted before, including

Table 1—General resources

Table 2—Compiled sources

Table 3—Original sources

Table 4—Reference tools

Table 5—Periodical, news, and networking sources

Table 1 identifies some of the major websites available for family history research. A few of the sites are megasites, providing links to many other sites. One can use the sites in Table 1 to access both compiled and original sources, as well as reference tools, for a variety of geographic areas.

Compiled Sources

Compiled sources, as described earlier, are used to identify research previously done. Table 2 contains a list of compiled sources commonly used to identify previous research, along with the finding aids used to access the sources (e.g., library catalogs may be used to locate family

histories). Six types of compiled sources are described, including

- Biographies
- Family histories and genealogies
- Local histories
- Pedigrees
- Query services
- Society and association resources

The latter two categories, “Query services” and “Society and association resources,” may be thought of more as finding aids, but are included here since they can direct one to compiled sources that are important in the research process. Each of the six types of compiled sources is described below.

Biographies

A biography is “A history of an individual’s life.”^[30] An early index of biographies, by Freemont Rider, consolidated all American biographical–genealogical records. This index has been published in two series:

- 1st series, *American Genealogical Index*, 1942–1952.^[9]
- 2nd series, *The American Genealogical-Biographical Index to American Genealogical, Biographical, and Local History Materials*, 1952–2000 (with supplements).^[9]

A large international biographical resource, the World Biographical Information System, currently provides access to over 6 million biographical entries (see Table 2).

Family histories and genealogies

A family history is defined as “A recorded account of the events occurring in one or more generations of a family.”^[30] A genealogy is “A published account of an individual’s ancestors, descendants, or both.”^[30] These terms are sometimes used interchangeably. Family histories and genealogies are published both as books and as articles in periodicals, in print and online, and may include only basic genealogical information or a longer narrative history of the family and individuals.^[6] The growth in family histories may be seen in the following figures:

- 1698—First genealogy in the United States (Byrd family)^[9]
- 1862—108 family histories available (from a bibliography by William H. Whitmore)^[9]
- 1982—50,000 family histories available (estimated by Willard Heiss)^[8]

One can search for genealogies and family histories in online catalogs, using subject terms such as “Jones family.” Three large online catalogs providing access to numerous family histories are identified in Table 2: the Library of Congress Online Catalog, the FamilySearch Catalog, and WorldCat. A useful resource for identifying family histories in the periodical literature is the *Periodical Source Index* (see Table 2).

Family histories are being digitized in growing numbers. Family History Books is a collection of over 325,000 digitized genealogy and family history publications on the FamilySearch website. The resources come from several partner institutions, including the Allen County Public Library, Brigham Young University, the Houston Public Library, and the Family History Library in Salt Lake City.^[31]

As family histories become digitized and searchable, massive amounts of text will be available online and the need to search effectively will increase. A dissertation designed to identify properties of family history literature

applicable to full text searching was completed by Molto relevant to this issue. Several properties of the literature were identified, including differences between male and female search term patterns. These differences would suggest gender-specific strategies when searching a full text family history database.^[32,33]

Local histories

A local history is “An account of the historical events surrounding a particular area.”^[30] Local histories include county histories, as well as histories of particular communities. These resources are helpful in family history research, since they usually contain information about early residents of an area, especially those prominent in the community. The growth in local histories may be seen in the following figures:

- 1848—First county history in America published (County of Westchester, New York)^[9]
- 1862—62 local histories available (from a bibliography by William H. Whitmore)^[9]
- 1975—90,000 local histories available (from a bibliography by Marion J. Kaminkow)^[8,9]

As with family histories, one can locate local histories through online catalogs, such as WorldCat (see Table 2).

One would search the catalog under a subject term, such as “Los Angeles (Calif.)—History,” or “Stuttgart (Germany)—Genealogy.”

Pedigrees

A pedigree chart, sometimes also referred to as a family tree, is “A chart that shows an individual’s direct ancestors, [including] parents, grandparents, great-grandparents, and so forth. A pedigree chart may contain birth, marriage, and death information.”^[30] Pedigrees are available on many websites, including the FamilySearch website. Three FamilySearch resources that include extensive pedigrees are the Ancestral File, the Pedigree Resource File, and Family Tree (see Table 2). The websites listed in Table 1 provide additional possibilities for locating pedigrees.

Query services

A query, relevant to family history, is “A request for information, such as information about a particular ancestor.”^[30] A query service provides a medium (e.g., via a message board) for communicating with individuals researching or wanting information on the same person. Forums are a variation of a query service, allowing one to read or post comments about a particular family or individual. Query services are available through various websites, including Ancestry.com and WorldGenWeb Project (see Table 2). Query services are frequently hosted by genealogical societies and family associations, and query lists can be found in genealogical periodicals relevant to one’s area of research.

Society and association resources

Genealogical and historical societies, such as the National Genealogical Society (United States), publish and archive numerous compiled resources (see Table 2). The societies often publish periodicals, which include family and local histories. They also gather pedigrees and genealogies from members of the organization, and house these materials in libraries or post the information on websites. Family and surname associations, likewise, provide access to compiled resources (e.g., pedigrees and histories), collected from members of the association (see Table 2). Directories can be used to identify societies and associations relevant to the ethnic group, locality, or surname being researched (see Table 4).

Original Sources

Once previously completed research has been identified, one can use original sources to verify the information or to extend what is known. Original sources, as previously described, contain information recorded near the time of

the event. Examples of original sources include birth records, marriage records, death records, probate records, land purchase records, census enumeration records, and pension records.^[6] Some original records have been copied, in whole or in part, forming new resources known as abstracts, extracts, transcripts, or translations.^[6] Indexes and other finding aids must be used to locate names in the original sources. More and more original records are becoming viewable and searchable online through digitization and massive indexing projects.

Tables 1 and 3 list resources that will assist one in locating original sources. Table 1 identifies general resources and Table 3 identifies resources pertaining to specific countries, geographic areas, and ethnic groups. Umbrella websites will direct one to other sites for the relevant information. Not all countries are included in Table 3, due to space limitations, but websites for major regions (e.g., Africa) will direct one to resources within that region.

Original sources are generally housed in archives. An archive is “A place where institutions such as governments, businesses, and churches keep their records and official documents.”^[30] Government sources (e.g., census records) are housed on either the national, state (or equivalent), or local level. For example, in the United States, the National Archives and Records Administration houses federal records, whereas the Massachusetts State Archive

would house records pertaining to Massachusetts. Nongovernment sources are housed in repositories relevant to the organization. Church records, for example, would be housed by the local church or in a regional repository for the particular denomination.

The Family History Library in Salt Lake City maintains a vast repository of microfilmed and digitized records. The records are copies of original church, government, and other archival resources from throughout the world.^[29] Access to the Library's microfilmed records is available at over 4700 branch FamilySearch centers located worldwide. The digital records can be viewed on the FamilySearch website. The Family History Library is managed by FamilySearch, previously known as the Genealogical Society of Utah which dates back to 1894.^[34,35]

Following is a description of the major types of original records.

Vital records and civil registration

Vital records are “...birth, marriage, divorce, and death records created by governments.”^[30] Civil registration is an alternate term used in many countries to refer to the process of keeping vital records. These records are especially important in genealogical research, since they document dates and places of birth, death, and marriage.^[29] Vital records, however, have not been kept until fairly recently

in some countries. In Great Britain, for example, civil registration began in 1837.^[17] Most government offices now keep vital records, and indexes to these records are available online for many countries (see Tables 1 and 3).

The following sources, described in Table 3 (International section), will direct one to vital records in specific countries:

International Vital Records Handbook
Vitalrec.com

National archives in various countries can also provide information on how and where to obtain vital records, as can the country-specific articles available on the FamilySearch Wiki.^[36]

Church records

Church records are “Records kept by religious institutions.”^[30] Churches usually keep records of their christenings, baptisms, confirmations, marriages, and burials.^[29] In some countries, especially those with state churches, church records are the most significant source for documenting births, deaths, and marriages in earlier time periods, since civil vital records were often not begun until the mid- to late 1800s. Information on church records in specific countries is available on the FamilySearch Wiki, in the country-specific articles.^[36]

Cemetery records

Cemetery records include records kept by cemeteries, as well as information from headstones. Cemetery records and headstones contain names, birth dates, and death dates. One can often identify members of families in these records, since family members are usually buried near each other. Epitaphs may help establish the relationships between individuals.^[29] The Find a Grave website is an excellent resource for viewing and searching headstone information (see Table 3). Information on cemetery records in specific countries is available on the FamilySearch Wiki, in the country-specific articles.^[36]

Census records

A census is “An official count and description of the people living in a country, colony, state, county, township, or city.”^[30] Most national governments conduct periodic censuses. In the United States, the 1850 census was the first to list every member of a household, by name, sex, age, country or state of birth, and occupation. Census records are helpful in determining where one’s ancestors lived.^[29] Census information is available online for some countries (see Tables 1 and 3). Information on census records in specific countries is also available on the FamilySearch Wiki, in the country-specific articles.^[36]

Probate records

Probate records are “Legal documents dealing with the distribution of an individual’s property after his or her death.”^[30] Probate records may contain a copy of a person’s will, if one exists, as well as names of family members and their relationships.^[29] In some countries and time periods, people did not generally own property, so probate records are not available. Information on probate records in specific countries is available on the FamilySearch Wiki, in the country-specific articles.^[36]

Military records

Military records are “Records detailing an individual’s service in a country’s armed forces.”^[30] The kinds of military records available vary by country, but may include service records, draft or conscription records, records of regular military forces, and veterans’ benefit records. Indexes to a growing number of military records are available online (see Tables 1 and 3). Information on military records in specific countries is available on the FamilySearch Wiki, in the country-specific articles.^[36]

Immigration and emigration records

Immigration records are “Records that document a person’s arrival into a country.”^[30] Emigration records are “Record[s] documenting an individual’s move to a different country.”^[30] Examples of these records include passenger lists, permissions to emigrate, and records of passports issued. Especially important are the passenger lists,^[37] for which indexes are available online, through services such as Ancestry.com (see Table 1).

A helpful resource for tracing an ancestor’s town of origin is Tracing immigrant origins, available on the FamilySearch Wiki. The following advice is given:

“The best approach is to start searching records created in the immigrant’s new country, especially if you know little about the person. Only rarely is it better to use country-of-origin records first... Obituaries are an excellent source of biographical information about immigrants... Even if a place of origin is not given, an obituary may provide additional research clues... ”^[37]

Useful links for immigration and emigration information are found in the following resource: Emigration and Immigration Records and Resources (see Table 3). Information relevant to specific countries is available on the FamilySearch Wiki, in the country-specific articles.^[36]

Other original records

Other types of original records include court, land, naturalization, taxation, business, medical, and school records. One should check all jurisdictions (e.g., town,

county, state, and country) that may have kept records about one's ancestor.^[29] Detailed descriptions of the many kinds of records available for specific countries can be found on the FamilySearch Wiki, in the country-specific articles.^[36]

Reference Tools

Reference tools are often divided into two types: background information and finding aids. Each type is discussed here.

Background information

Reference tools that are useful in providing background information in the research process include^[6]

- Guides
- How-to resources
- Maps and gazetteers

A growing number of guides and how-to resources for genealogy have become available. Table 4 includes descriptions of some of these, including guides to research in particular countries. An example is Greenwood's *The Researcher's Guide to American Genealogy*. The Research Selection Tables, available on the FamilySearch Wiki, also provide research guidance, by country, state, and equivalent areas, including detailed information about which resources to use to find specific information about one's ancestors (see Table 4).

A basic how-to resource, listed in Table 4, is *Genealogy Online for Dummies*, by Helm and Helm. This resource provides an introduction to genealogical research. Other how-to resources from Table 4 include a citation guide, standards guides for establishing proof in genealogical research, a handwriting guide, and a reference to online classes. A prime source of information for maps and gazetteers (geographical dictionaries) is the Perry-Castañeda Library Map Collection, with links to maps from throughout the world (see Table 4).

Finding aids

Reference tools that serve as finding aids for locating information in record collections include^[6]

- Bibliographies
- Catalogs
- Directories
- Indexes

Several finding aids are identified in Table 4, along with some additional references in Tables 2 and 5. Bibliographies, though not listed in the tables, are a useful finding aid for identifying published family histories.

The following bibliographies, edited by Kaminkow and by Filby, are classics in the genealogical literature:

- 1970—*American and British Genealogy and Heraldry*, by Filby^[9]
- 1972–[1987]—*Genealogies in the Library of Congress* (including supplements) by Kaminkow^[9]
- 1981—*A Complement to Genealogies in the Library of Congress*, by Kaminkow^[9]

Library catalogs (listed in Table 2) are another type of finding aid for locating family histories and local histories. Directories (listed in Table 4) are helpful in identifying societies, libraries, museums, software, and other items of genealogical interest. Indexes, finally, are a finding aid that is useful for searching the periodical literature. Examples of periodical indexes are provided in the next section and in Table 5.

PERIODICAL, NEWS, AND NETWORKING SOURCES

A periodical is defined as “A periodical publication... with a fixed interval between the issues or numbers.”^[13] Periodicals often contain all three types of resources discussed earlier: compiled and original sources, as well as reference tools. Periodicals are available for specific countries, regions, and ethnic groups, as well as for other topics relevant to genealogy. Examples of several genealogical periodicals are provided in Table 5.

Society periodicals

Bidlack notes “At least half the genealogical journals and books being published today come from societies.... Below the state level there are scores of genealogical societies that publish periodicals devoted, usually, to a county.”^[8] Two of the earliest society periodicals, relevant to the United States, are

1. 1847—*The New England Historical and Genealogical Register*—oldest continuing genealogical periodical in the United States.^[8]
2. 1912—*National Genealogical Society Quarterly*—including primary source material from throughout the United States.^[8]

Non-society periodicals

Many non-society genealogical periodicals are also available. A periodical focusing on computers and technology in genealogy is *Internet Genealogy* (see Table 5). An example of a scholarly genealogical periodical is *The American Genealogist*, whereas a periodical useful for practical advice is *Family Tree Magazine* (see Table 5).

Periodical indexes

Indexes are important in providing access to the information found in genealogical periodicals. Jacobus produced the first index to periodicals, with others continuing his work in subsequent years:

- 1932–1953—*Index to Genealogical Periodicals*, by Donald Lines Jacobus^[9]
- 1957–1963—*Annual Index to Genealogical Periodicals & Family Histories*, by Inez Waldenmaier^[9]
- 1963–[2002]—*Genealogical Periodical Annual Index*, by various editors^[9]
- 1987–present—*Periodical Source Index (PERSI)* (see Table 5)

The *Periodical Source Index* is the most comprehensive and up to date of the genealogical periodical indexes and may be accessed online from two vendors, with a growing number of links to articles that have been digitized (see Table 5).

News and networking

Periodicals and blogs are important sources for genealogical news. A blog is “a website that contains online personal reflections, comments, and often hyperlinks, videos, and photographs provided by the writer.”^[13] Blogs are especially useful for news, since they are often updated daily. Two genealogical blogs are described in Table 5: Eastman’s *Online Genealogy Newsletter*, and the *GenealogyBlog*. Various social networking tools are also available for genealogists, for communicating with other researchers and for obtaining research advice (e.g., via podcasts and wikis). A FamilySearch Wiki article, entitled “Popular social networks for genealogists,” describes these tools (see Table 5).

CONCLUSION

Interest in genealogy began in antiquity, with references to genealogical records found in both the Old and New Testaments. During the earlier periods, those tracing their genealogies were often interested in proving their nobility. In the United States, it was not until the 1970s that interest expanded to people of all classes and ethnic groups. The availability of printed records, from which to derive accurate genealogies, did not exist in some countries until the mid-1500s, with civil records not available until the 1700s and 1800s. Genealogy as a scholarly pursuit came into being in the 1930s in the United States. Since then, a growing number of resources have become available, including microfilmed and digitized records. The Internet has revolutionized the way research is done, by providing access to genealogical resources from one’s home

computer. Genealogy is the second most popular hobby in the United States.

A growing number of user studies have been conducted to determine how genealogists perform their work. There is a need, however, for further research relevant to the growing use of the Internet in genealogical research. One concern relates to how genealogists can effectively navigate the Internet to access the many resources now available. More studies are also needed relating to the novice genealogist, since previous studies have focused on the professional.

Genre Theory and Research

Catherine F. Schryer

Department of English Language and Literature, University of Waterloo, Waterloo, Ontario, Canada

Abstract

This entry provides overviews on current genre theory and research that investigates texts in their social contexts. Specifically, the entry focuses on relevant theory in Rhetorical genre studies and Linguistics and provides illustrations from applied studies in Professional Communication and Composition research. Since much current research in genre theory utilizes social theories that deal with questions of structure and agency, relevant theories in that area are reviewed as well. Finally, the entry notes some of the pedagogical implications of genre research.

Information Studies scholars such as Andersen^[1] have recognized the importance of the concept of genre especially for scholars in information disciplines. Andersen points out that the term genre does not just encompass classification of text types. Rather he suggests that using a nuanced understanding of genre to refer to “situated and typified document production and use” can assist researchers to have a “more informed understanding of the ways in which information systems help, or fail to help people in their work” (p. 341). In fact, from a variety of perspectives genre researchers have developed theoretical and methodological tools to investigate texts in their social contexts. This research could assist information discipline scholars in enriching their own understanding of the important social action of categorization.

This entry provides overviews into the two main areas investigating the concept of genre: Rhetorical genre studies (RGS) and Linguistics. Because genre scholars are concerned with the interaction between texts and their social contexts, some relevant social theories are also described. Finally, since many investigations into genre have occurred in educational or workplace settings devoted to training, several theories of particular importance to teaching and learning are also reviewed.

RHETORICAL GENRE STUDIES

Rhetorical genre studies surfaced in the North American academy in the early 1980s and was adopted and refined by researchers particularly in professional communication who recognized its importance for investigating workplace communication practices. From the RGS perspective, either genres are not just classifications of texts (such as poetry versus the novel) or classification itself as an enterprise means much more than simply slotting texts into various categories. As its name suggests, RGS

began among rhetorical scholars namely Bitzer,^[2] Campbell and Jamieson^[3] and most importantly, Miller^[4] in reaction to traditional rigid systems of classifying texts according to regularly occurring features. Classical rhetoricians, Aristotle^[5] for example, designated persuasive texts into one of three categories. A text or speech could be forensic, epideictic, or deliberative. Thus, forensic discourse tended to occur in law courts and focus on past actions in order to determine guilt or innocence; epideictic speeches, associated with the present, emerged in ceremonial occasions such as weddings or funerals and elaborated on praising or blaming an individual; and deliberative performances occurred in political venues and were intended to move their audiences to future action. This system, as useful as it might have been for classical rhetoricians, breaks down in the face of complex modern texts such as a report that might combine a forensic analysis of a problem together with a deliberative plan to address the problem. Nor does it account for the various ways that a report might appear in different organizations. In fact, what a report entails can differ significantly in government agencies, engineering companies, or hospitals. And yet people in these organizations do classify oral events and written documents such as reports and know among themselves what they mean and expect in a meeting, interview, case presentation, record, consultation letter, or any of the other multitudinous tasks that people accomplish in their daily lives.

Miller asserted that genres were, in fact, forms of social action—that they functioned to coordinate the work of organizations or to accomplish some kind of significant task for individuals. Miller based this argument on Campbell and Jamieson’s insight that “a genre does not consist merely of a series of acts in which certain rhetorical forms recur. . . Instead a genre is composed of a constellation of recognizable forms driven by an internal dynamic” (p. 21). As Miller explains, this sense of an “internal dynamic” is

crucial because it conveys the sense that these language events emerge as fusions of substantive and stylistic features in response to specific situations. Using Bitzer's notion of "exigence," Miller suggests that people in their social networks or contexts over time both recognize the need to respond (exigence) to specific situations and to typify those situations. For example, healthcare workers have long recognized the need to record their observations, consult with experts, and transfer information about patients in order to accomplish their work. Over time these practitioners developed ways to handle these needs and these strategies evolved into recognizable text types or oral speech events such as patient records, consultation letters, and case presentations. These already existing structures, fusions of content, style and organization, now facilitate practice in these settings, and newcomers have to learn how to wield them in order to get their work done.

Miller's insights were important for several reasons. She recognized the pragmatic function of genres (they get work done) and that this work occurred in social settings such as workplaces and not just in literary texts. She argued that genres constitute epistemological categories (types evolved and created by their users) and were composed of sets of content, stylistic features, and organizational structures that tended to re-occur within these typified events. In short, Miller's reconceptualization of genre as a theoretical concept opened the way for professional communication researchers to investigate texts in their social contexts. Researchers who operationalized and refined Miller's insights include Winsor^[6] and Artemeva^[7] in engineering, Smart,^[8] Orlikowski and Yates,^[9] and Schryer^[10] in business communication, Spinuzzi^[11] in software development, and Devitt^[12] and Bawarshi^[13] in composition studies.

Another important source for the renovation of genre theory was the work of Bakhtin^[14] and his circle including Volosinov.^[15] Although Bakhtin developed his ideas during the 1920s and into the 1930s (and mostly in reaction to de Saussurean linguistics and literary formalism) his dynamic ways of thinking about language did not enter into the North American academy until the 1970s and even the 1980s. Rhetoricians such as Bialostosky,^[16] Kent,^[17] Klancher,^[18] anthropological linguists such as Hanks,^[19] and professional communication researchers such as Schryer,^[20] Cross,^[21] Berkenkotter and Huckin^[22] recognized the relevance of Bakhtin's insights for investigating texts in their contexts. As Dentith^[23] notes, central to Bakhtin's thought is the basic principle "that communicative acts only have meaning, only take on their specific force and weight, in particular situations or contexts" (p. 3).

Two key terms—utterance and speech genre—evoke Bakhtin's dynamic way of conceptualizing language and constitute his major contribution to genre theory. As he explains in "The Problem of Speech Genres," the primary unit of communication is not the sentence or the word but

the utterance. The utterance is "individual" and "concrete" and generated by participants in the "various areas of human activity" (p. 60). The utterance is inherently, he suggests, addressing and responding to another person or collective of people. This understanding of language stands in direct opposition to traditional linguists (such as de Saussure) who see language as an objective system with classifiable elements (*langue*) that the writer or speaker operationalizes (pp. 67–69). Instead Bakhtin sees that as we speak or write we are always shaping our language for real or imagined others. For example, a dictionary definition of the word *right* would indicate that it is an adjective meaning *correct*. However, note what happens in the following conversations.

1. A mother and teen-aged daughter are watching TV.
 Mother: Doesn't he (referring to news anchor) look good today?
 Daughter: Yeah, right (said quickly, emphatically, and sarcastically).
2. A mother is driving her adult son back to his apartment. He is a doctoral student trying to finish his dissertation.
 Son: You know, my advisor tells me that I have to produce three publishable articles before I complete my dissertation. So I think I am going to have to take an extra year to get everything done.
 Mother: Right (said very slowly while she nods her head).

In the first instance *right* does not mean correct but might mean something like *you must be out of your mind*. In the second instance *right* might mean something like *I respect your decision but can see some financial implications that we will have to discuss later*. The utterance captures this process wherein speakers and listeners, writers and readers, inflect on the fly their language to mean something appropriate for that person and that situation. Furthermore, as these examples suggest, an utterance "is a link in a very complexly organized chain of other utterances" (p. 69). The utterance *right* is a response to an utterance and could generate a host of other utterances.

This profoundly situated understanding of language might suggest that for Bakhtin communication is indeterminate and chaotic. However the concept of "speech genre" provides a balance. He suggests that although utterances are individual "each sphere in which language is used develops its own *relatively stable types* of these utterances" which he calls "*speech genres*" (original emphasis, p. 60). He indicates that genres are heterogeneous and range from "short rejoinders of daily dialogue...to the fairly variegated repertoire of business documents" and include the "diverse forms of scientific statements and all literary genres" (pp. 60–61). Bakhtin's theory can accommodate this diversity because he posits that speech genres are both centrifugal and centripetal.

The centrifugal quality of utterances or speech genres refers to the forces of change (de-normalizing, clowning, or mimicry) that occur within text types; whereas the centripetal quality refers to the social forces that attempt to keep an utterance stable. An important feature of Bakhtin's thought is that both actions (stabilizing and destabilizing) co-occur within utterances.

Because of their very heterogeneity, speech genres can be difficult to identify. However, Bakhtin provides some features that allow researchers to argue that a specific language event could be defined as participating in a genre. He notes that a change of speaking subjects or a sense of *finalization* marks the boundary of a speech genre (p. 76). Like Miller, Bakhtin sees that agents in their social milieus simply know when a speech event has been accomplished and when or if they can interrupt and start a new utterance or chain of utterances. Bakhtin points to three aspects whereby social agents can recognize that the speech event is complete and that they can respond: "1) semantic exhaustiveness of the theme; 2) the speaker's plan or speech will; and 3) typical compositional and generic forms of finalization" (pp. 76–77). In some contexts such as the military, the semantic resources can be limited (for example requests and orders) whereas in other contexts semantic resources can be rich as in creative or scientific endeavors. His understanding of genres as affected by the speaker's plan is particularly interesting as he suggests that speakers and listeners together enact a genre. He explains "We learn to cast our speech in generic forms and, when hearing others' speech, we guess its genre from the very first words; we predict a certain length. . . and a certain compositional structure; we foresee the end" (p. 79). In a way genres function very much like a piece of jazz. When the first performer lays down the track or musical line, the other performers improvise around it, and all the performers know by listening and looking at each other when the piece is completed. Many of our daily language events such as interviews, condolence letters, and classroom interactions have this felt sense of improvisation within structure. As Kent^[17] explains, genres are like "guessing games we employ in order to produce utterances and to understand the utterances of others" (p. 46).

Finally, Bakhtin indicates that "typical compositional and generic forms" (p. 77) mark specific genres. In some contexts, especially those associated with power, these typical features can seem regulated, "compulsory and extremely stable" (p. 79). But in most situations genres are "flexible, plastic, and free" (p. 79). In other words, speakers and writers, when they launch into a genre, do not actually know which strategies they will use to accomplish their purpose but they also tend to stay within a generic range so as to accommodate their readers' or listeners' expectations.

Bakhtin's insights into genre shifted the ground for communication researchers in several important ways. First, his work obviously extends concepts of genre far

beyond literary texts into examining the powerful genres such as records, reports, and letters that constitute our social worlds. Secondly, his insights, like those of Miller's, offer a way to theorize the process of classifying utterances. It really matters how social agents classify their text types or speech events. These classifications tell researchers a great deal about what a group values and recognizes as assisting in accomplishing its social purposes. At the same time, however, these same utterances are not simply instances of a category. Because each instance of a genre is addressed to a different context, audience, and time, it evokes a different set of strategies within an acceptable (to participants) range. In effect, genres are abstractions or ever changing sets of socially accepted strategies that participants can use to improvise their responses to a particular situation. As I^[20] suggested in an early study of veterinary medical records, genres are "stabilized-for-now or stabilized enough sites of social and ideological action" (p. 200). This definition expresses the sense that genres are just stabilized enough so that agents can accomplish their social purposes but that genres are constantly evolving. Finally, Bakhtin's work suggests that utterances or genres are the socially situated ways that we learn to communicate. Rather like a singer who learns to sing by singing songs, we all learn to communicate through these constellations of resources.

RGS researchers, using a range of qualitative methods, have profited from a synthesis of Miller's and Bakhtin insights into order to investigate the social contexts that both structure and are structured by specific texts. To name just a few, Smart's^[8] work has investigated reading and revision practices associated with banking; Hanks^[19] has investigated historical government documents; and Bazerman^[24] and Spinuzzi^[11] have explored genres as existing in networks or systems.

GENRE RESEARCH IN LINGUISTICS

Although both RGS and genre researchers in linguistics recognize the relationship between texts and their social contexts, it is fair to say that RGS has often concentrated on investigating the social practices associated with text types; whereas genre research in linguistics has often focused on analyzing the textual features found in various text types. The development of genre studies has also experienced more controversy in linguistics than it has in RGS.

In fact, the recognition of the dynamic interaction between texts and their social contexts captures an intense debate that has been occurring within linguistics. For some time, applied and critical linguists have disparaged each other's projects. Applied linguists, mostly from the systemic functional linguistic (SFL) tradition, have critiqued critical discourse analysis (CDA) for its failure to

develop rigorous methodologies, especially in terms of precise terminology for analyzing text.

According to Chapelle,^[25] SFL views “language as a social semiotic a resource people use to accomplish their purposes by expressing meanings in context.” Although SFL provides ways to analyze syntactic structures, as a theory it insists that the functions of language are central. Consequently, the dynamic interaction between social contexts and language are central for SFL. Much of SFL stems from the work of Halliday and his many collaborators.^[26,27]

As Wodak^[28] explains, CDA involves “an interdisciplinary approach to language study with a critical point of view” for the purpose of studying “language behavior in natural speech situations of social relevance.” Kress^[29] notes that CDA differs from other forms of linguistic analysis as it has an overt political agenda—exposing relations of power.

Luke^[30] for example, points out that CDA does not have a consistent taxonomy. The CDA researchers such as Young and Harrison,^[31] on the other hand, have challenged SFL to move beyond descriptions of linguistic structures to accounts that provide a “social critique by documenting structures of inequality” (p. 2).

The terms of this debate are echoed in applied linguistic genre research. Applied linguists, especially those interested in issues related to second language learning, literacy, and pedagogy have found the concept of genre particularly useful. One group, especially associated with English for Specific Purposes (ESP) (much of the ESP understanding of genre derives from Swales^[32] focus on text types as characterized by specific organizational structures or moves), has provided detailed descriptions of the moves or “schematic structures”^[33] within genres as diverse as the research article,^[34] grant proposals,^[34,35] and business letters.^[36] Another group, more influenced by SFL, has emphasized the social purposes of genres and has sought to explain not only the moves of specific genres but also lexical, grammatical, and cohesive patterns. The work of Cope and Kalantzis^[37] and Martin^[38] has contributed significantly to this group, often called the Sydney School. This school, in particular, points to the pedagogical implications of genre research and claims that the often tacit rhetorical and linguistic choices within powerful genres need demystification for those with less access to privileged forms of education. Consequently, these scholars call for more overt teaching of genres in order to resolve this inequity.

The Sydney School also critiques RGS researchers on two counts. They note that North American genre researchers through their dependence on qualitative studies have focused on exploring social context rather than texts and that RGS has failed to link genre research to pedagogical issues. RGS advocates, on the other hand, have critiqued linguistic genre research, especially the Sydney School, for abstracting genres from their social contexts and attempting to codify them.^[39] The pedagogy

associated with this type of research, they suggest, fails to address issues related to situated learning. Gee et al.^[40] effectively dramatize the issue by pointing to the discourses associated with law school. They point out that law students are not directly taught the strategies associated with legal discourse. Rather they are subjected to an immersion program wherein they learn “inside the procedures, rather than overtly about them” (p. 13). This immersion program works for two reasons. First, as Gee et al. point out, trying to spell out the rules of the game involved in doing law would only offer a “panacea” (p. 12). They assert that, “All that goes into thinking, acting, believing, valuing, dressing, interacting, reading, and writing *like a lawyer* cannot be put overtly into words” (p. 12) and the attempt to codify all these strategies would produce stilted performances. Secondly, learning inside procedures ensures that a learner “takes on perspectives, adopts a worldview, accepts a set of core values and masters an identity without a great deal of critical and reflective awareness” (p. 13). No field or organization wants its newcomers to question its basic values as such questioning would undermine the kinds of “fluent and fluid performances” (p. 13) that mark a speaker as a member of a field. Of course, Gee et al. suggest that field-specific discourses should be critiqued but not during the process of acquiring them.

Critical Discourse Analysts critique both RGS and other linguistic projects for being too descriptive and for failing to deal with issues of power and hegemony. As Luke^[30] explains CDA advocates for “principled reading positions and practices for the critical analysis of the place and force of language, discourse, text, and image in changing contemporary social, economic, and cultural conditions” (p. 97). In fact, what sets CDA analyses apart is their, as Luke explains, “attempt to inform text analyses with broader social theory” (p. 101). This emphasis has resulted in diverse studies of public discourse,^[41,42] racism,^[43] and organizational discourse^[44] that focus on issues of power and hegemony.

Until recently, RGS scholars, genre researchers in applied linguistics, and CDA scholars have not been addressing each other’s research. In fact, these groups all offer useful resources for genre-focused projects. Genre research can only profit from a combination of RGS with its strong commitment to rigorous qualitative studies and the rich development of linguistic concepts in the work of Swales,^[33] Hodge and Kress,^[45] Stillar,^[46] Hyland,^[32] and Giltrow.^[47]

SOCIAL CONTEXT THEORIES

Much of the integration within genre studies has been made possible by the incorporation of the social theories exploring the relationship between structure and agency. Genre research has always struggled with issues of

agency. Critics of genre theory have complained that the concept of genre implies rigid discourse structures that impose actions on agents. In order to develop models of research that negotiate the difficult terrain between power, social structures, and agency, some genre researchers have turned to the theoretical and methodological resources present in social theories such as those of Giddens,^[48,49] Bourdieu^[50,51] and Engeström^[52,53] that investigate the dynamic between agents (readers and writers), their products (genres), and social contexts. Central to Giddens'^[50] work, for instance, is his insistence on the "mutual dependence of structure and agency" (p. 122). Giddens rejects structuralist and functionalist notions that conceptualize social structures as abstract systems outside of time. Such accounts describe agents as either fully in control of their own operations or as fully subject to their social contexts. For example, in de Saussurean linguistics, language users are conceptualized as fully in control of their language systems; whereas in Levi-Straussian structuralism, agents are at the mercy of systems (such as systems of myths) which compel them to articulate essentially the same structure (despite discrepant details). Neither account explains, in Giddens' view, the complex and nuanced way that human agents are affected by and reproduce their social environments. Rather Giddens suggests that agents bring with them their memories of past experiences and/or they use already existing structures—such as reports, meetings, memos, patient records, etc.—to guide them in their interactions with other social agents. These already constructed social structures are filled with "rules" or the resources and constraints that enable and constrain the constant reproduction of social life. However, as Giddens explains, these "rules" are not like the rigid rules present in a game of chess. Rather they are more fluid, emergent and dependent on the collective agreement of those involved in the interaction (pp. 118–120). He also asserts that agents can change these social structures in the midst of social interaction. As he puts it, "*All reproduction is necessarily production, however; and the seed of change is there in every act which contributes towards the production of any 'ordered' form of social life*" (p. 101, emphasis in original). For Giddens, in fact, all social contexts are ordered but changing social accomplishments—constantly being co-constructed by social agents.

Giddens' insights help explain how relationships exist between texts and their social contexts. For instance, my interdisciplinary research group^[54] investigated the effect of medical case presentations on new physicians. We noted that the case presentation preexists the students who use it. It is filled with rules and resources that both constrain and enable the performance of their cases. These rules and resources resonated with professional attitudes and values. At the same time the case presentation can only exist if users reproduce it, and no case

presentation ever uses the exact same rules and resources as another case presentation even in the same setting even though the users recognize the case presentation as a recurrent event.

Giddens also offers useful methodological insights. He parallels his focus on agency with an insistence that agents "are able to explain most of what they do, if asked" (p. 93). Researchers need to include participant information in their data collection because social agents have access to both discursive and practical knowledge about their routine activities. Social agents, according to Giddens, are reflexively monitoring their own activities and have valuable explanations (discursive knowledge) of their practices. At the same time agents have tacit, "practical knowledge" or "knowledge embodied in what actors 'know how to do'" (p. 126) in their daily activities. Consequently, researchers need to develop methodologies that capture both kinds of knowledge.

My own work^[55] and others such as Yates and Orlikowski^[56,57] have profited from Giddens's insights. For instance, my interdisciplinary research group^[55] also investigated the resources and constraints associated with forensic letters written by physicians charged with providing an opinion as to whether a child had experienced abuse or neglect. We identified many regular features associated with these letters and yet no two of these letters are the same. Yates and Orlikowski^[56] also draw on a combination of rhetorical and structuration theories when they observe that workplaces genres such as the memo, the proposal, and the meeting are organizational genres "embedded in social processes" (p. 299) and that genres such as email both shape and are shaped by discursive practices in workplaces.^[57]

Another social theorist, Bourdieu, offers significant theoretical and methodological insights in terms of addressing issues of power. For Bourdieu, the most important aspect of social agents is that they are *social* or inhabited by "habitus." Bourdieu^[52] defines habitus as "socialized subjectivity" (p. 126). As Wacquant,^[52] one of Bourdieu's main collaborators, explains, the habitus "consists of a set of historical relations 'deposited' within individual bodies in the form of mental and corporeal schemata of perception, appreciation and action" (p. 16). Habitus, thus, is not a passive kind of socialization; it produces an active engagement wherein social agents, because of their prior experiences, recognize how to respond appropriately and even strategically to "fields" (p. 14) or specific social contexts. To respond agents must have a range of resources that predispose them to react appropriately. Thus, for example, healthcare fields accept students from academic programs that predispose them to work within healthcare paradigms. These professions or fields then further shape students to perceive, communicate, and behave in professional or acceptable ways.

The concept of "field" or "market" or "game" is central to Bourdieu's way of conceptualizing disciplines,

organizations, or social systems and their relationship to power. For Bourdieu,^[52] society is not a seamless totality, but rather an “ensemble of relatively autonomous spheres of play” (p. 17). He^[51] explains that a game, market, or field is a “structured space of positions in which the positions and their interrelations are determined by the distributions of different kinds of resources or capital” (p. 14).

In other words, agents are structured by their experiences within a field. At the same time they also structure or reproduce those fields but not in purely reductive ways. Rather, because agents occupy different positions within their fields (and thus have different access to power) and because fields themselves occupy different positions in relation to each other, agents enact different strategies (although only within a specific range). Bourdieu^[58] calls these regulated, improvisational strategies, triggered by the interaction between habitus and field, “the logic of practice” (p. 112).

Integral to habitus is linguistic habitus,^[52] or the improvisational communication strategies that agents use to enhance and distinguish their own position. Language, particularly that aspect of language called style, is deeply implicated in this struggle to succeed. Bourdieu observes that “style exists only in relation to agents endowed with schemes of perception and appreciation that enable them to constitute it as a set of systematic differences” (p. 39). Furthermore, this process of differentiation, or style production is deeply implicated in the reproduction of symbolic power. Bourdieu notes that:

This production of instruments of production, such as rhetorical devices, genres, legitimate styles, and manners and, more generally, all the formulations destined to be “authoritative” and to be cited as examples of “good usage,” confers on those who engage it a power over language (p. 58).

As instruments of production, some genres, especially those enacted by well-positioned agents in well-positioned fields such as medicine, can reproduce forms of symbolic power that can literally shape their receivers’ views of the world. From Bourdieu’s perspective, then, genres can be seen as constellations of regulated, improvisational strategies triggered by the interaction between individual socialization, or “habitus,” and an organization or “field.”

Bourdieu, like Giddens, also provides methodological insights. He suggests that two types of analyses are needed in order to uncover the structures that maintain and reproduce power.

First, we push aside mundane representations to construct the objective structures (spaces of *positions*), the distribution of socially efficient resources that define the external constraints bearing on interactions and representations. Second, we reintroduce the immediate, lived experience of agents in order to explicate the categories of perception and appreciation. (p. 11, emphasis in original)

From a genre perspective, the first step entails the close reading of a set of text types, suspected to be participating in a genre, in order to describe and critique the kinds of strategies evoked within this discursive event. Already existing terminology from linguistics can prove useful at this stage. The second step involves interviewing readers and writers and asking them for explanations for their strategies and problem-solving techniques.

Bourdieu’s insights resonate across much genre studies in work such as that done by Devitt^[12] and Bawarshi.^[13] My own work^[10] has certainly profited from Bourdieu’s work not only in terms of developing a critical perspective that can demonstrate that certain genres can enact forms of symbolic violence but also in terms of developing a methodology that can accommodate both linguistic and qualitative forms of analysis. Another researcher, Hanks,^[19] from linguistic anthropology, has done groundbreaking work integrating Bakhtin and Bourdieu in order to create a model to investigate historical genres of subjugation in fifteenth century Mexico.

Finally, activity theory has provided additional insights to explain the complex, dialectical interaction of agents, and their social structures. According to Vygotsky,^[59] activity theory emerged as a counterbalance to simplistic notions of socialization which either envisioned individual agents as self-contained preformed entities (psychological model) or as entities totally at the mercy of their environments (behaviorist model). Instead, Vygotsky envisioned agents as learning through using tools in purposeful, goal directed activities. He saw that these tools, both physical (hammers, pencils) and cultural (language, genres), preexist their users and mediate the interaction between agents and their social environments. By using tools, human agents internalized the values, practices, and beliefs associated with their social worlds. At the same time as they become experienced users, agents can, in the midst of purposeful activity, affect their social contexts or even modify their tools. Certainly in my group’s research,^[55] we saw that, by using the mediating tool of case presentations, healthcare students were internalizing the values and practices while involved in purposeful activities that would lead to their own ability to affect future social contexts (i.e., their ability to deal with their own future patients or clients).

Engeström^[52,53] and other researchers such as Cole,^[60] Scribner,^[61] and Wertsch^[62] have extended Vygotsky work into a model for the analysis of complex interactions between agents and social structures in professional and workplaces settings. While retaining the concepts of tools mediating the socialization of agents, they have expanded the analytical concepts within the notion of system to account for more of the dialectical, or rather dialogical, interactions that occur between social agents and between social agents and their settings. Engeström^[63] defines an activity system as a system “that incorporates both the object-oriented productive aspect and the person-oriented

communicative aspect of human conduct,” and he suggests that a human activity system, “always contains the subsystems of production, distribution, exchange, and consumption (p. 67).”

Research integrating theories of genre together with activity system theory include Bazerman,^[64] Russell,^[65] Artemeva,^[66] Spinuzzi,^[11,67] Yates and Orlowski,^[68] and Varpio^[69] among many others. Activity system theory has proved particularly valuable in terms of exploring “genre sets,”^[64] systems of genre,^[65,66] or genre repertoires,^[68] in order to explain the ways that text types affect each other and create hybrid forms. Activity theory has also proved useful in terms of investigating the ways that systems of genres interact with various technologies.^[69]

LEARNING THEORIES

As noted earlier, genre theorists have been debating the impact of their contextualized findings on education. Much of the debate has focused on whether genres should be taught directly at all. On one side of the debate are members of the Sydney School^[38] who insist that genres need to be directly taught. On the other side of the debate are RGS scholars such as Freedman^[70] and Dias et al. Dias et al.,^[71] for instance, in their thought provoking comparison of writing practices in the workplace and the academy claimed that the school genres of the academy were “worlds apart” (p. 3) from workplace genres. Reflecting the purposes of schooling, educational genres typically create the circumstances wherein “epistemic” or knowledge-making tasks are evaluated on an individual basis (p. 44). As Dias et al. explain, “Within the classroom context each paper is graded in comparison to all others, and the institution has a vested interest in a quality spread” (p. 62). Workplace genres, on the other hand, mediate the interactions of agents in different ways. In workplace settings, for example, managers will intervene in writing processes as “the institutional goal is to elicit the best possible product from each employee each time writing is undertaken” (p. 62). In fact, Dias et al. conclude that the activity systems of education and workplaces differ so radically, that educational institutions cannot claim to be teaching the genres of workplace communication. This perspective, of course, is deeply troubling to educators in professional communication^[72] who claim that the strategies that students learn in professional communication classrooms translate into useful practices in workplace settings.

Much of Dias et al.’s arguments stem from their understanding of activity theory and their realization that the activity systems of the workplace and education have inherently different purposes. However, their insights were also shaped by current research into learning theory particularly the concept of “communities of practice” (COP) as developed by Lave and Wenger^[73] and later refined by Wenger.^[74] This body of work focuses on

apprenticeship experiences. Lave and Wenger describe a COP as “a set of relations among persons, activity and world, over time and in relation with other tangential and overlapping COP” (p. 98). Lave and Wenger and their many supporters also insist that learning is a natural and ubiquitous phenomenon and that it occurs most naturally and effectively within COPs through the process of “legitimate peripheral participation” (p. 34). As Lave and Wenger explain, “learning is an integral part of generative social practice in the lived-in world” (p. 35) and occurs naturally and constantly in groups consisting of expert and inexperienced members. Less expert members learn through their involvement in legitimate (recognized by the group) practices. At first this involvement is peripheral (by observing, by being assigned part of the task, by being supervised) but eventually less expert members assume full participation in the group’s activities.

More recently, research has challenged the either/or nature of this debate. Researchers such as Artemeva et al.^[75] have pointed out that activity systems and COP overlap and that often strategies learned in one context can be transferred to another. Certainly Bourdieu’s work on linguistic habitus predicts this kind of movement. At the same time students can also be taught to see text types not as rigid formalizations but as constellations of strategies that they can adjust to different circumstances. In other words, students can be taught to be ‘savvy’ users of genres. This kind of pedagogy as advocated by Giltrow^[48] means^[1] getting students to see the regularities often associated with specific text types such as academic research papers,^[2] pointing to the range of different strategies that exist among different instances of the text types,^[3] explaining the often ideological reasons for certain strategies,^[4] and advocating that students chose their strategies according to the needs of their audience and situation rather than following a rote format.

CONCLUSION

This overview of research on genre theory and research can only provide snapshots of the rich discussions about genres or texts in their social contexts that are occurring in a variety of interdisciplinary settings. These discussions could be of value to researchers in the information sciences. Most importantly, they point to the important role of categorizing. As readers and writers, speakers and listeners, we anticipate (categorize) text types and improvise with each other on the fly. We are also constantly bringing resources from one text type to another and thus experiencing constant genre hybridity. In many ways information scientists are at the heart of much genre work as they often have to reflect in their categorization schemes the ever evolving social process that is genre.

Geographic Information Systems (GIS)

Timothy F. Leslie

Nigel M. Waters

Department of Geography and Geoinformation Science, George Mason University, Fairfax, Virginia, U.S.A.

Abstract

This entry, describing the world of geographic information systems (GIS), begins with a synopsis of the considerable academic debate over the classification of GIS as a tool or a science. The state of the art for GIS technology is described along with the current concern over the teaching of spatial thinking, a necessary prerequisite for the successful use of GIS. The importance of spatial autocorrelation in the statistical analysis of geographic data is explained. Recent developments including public participation GIS (PPGIS) and volunteer geographic information are recounted. The second part of the entry describes GIS applications and software packages along with the anticipated future for GIS. This entry concludes with a resource section that includes information on GIS Day and GIS conferences, journals, books, and organizations.

INTRODUCTION AND OVERVIEW

In 1998, *The Encyclopedia of Library and Information Science* published an entry on geographic information systems (GIS)^[1] that reviewed both the history and the body of knowledge associated with GIS. A sequel in 2001^[2] documented the progress made by the community during the following 3 years, with particular detail given to the “systems versus science” debate. For the sake of completeness and self-containment, this overview of the subject again begins with formal definitions of GIS. Next, the state of the art as it existed in 2008 is described. This is followed by a discussion of spatial thinking as conceptualized within the (generally American) educational system.

In recent years, GIS has come to represent a synthesis of science and application. The “systems versus science” debate has become passé. Internet applications have flourished, with many users unaware they were using GIS technology to create maps or obtain driving directions. This entry concludes with an overview of the near-term future of GIS and with a list of GIS resources, both online and traditional print materials. The present account does not provide a complete and comprehensive introduction to GIS, and readers wishing to learn the basics before consulting the rest of the entry are advised to go to the following online tutorials: the U.S. Geological Survey (USGS) GIS education Web site at <http://education.usgs.gov/common/lessons/gis.html> and the Environmental Systems Research Institute (ESRI) discussion of GIS presented at <http://www.gis.com/whatisgis/>. A comprehensive description of those topics belonging to the body of knowledge associated with GIS may be found in DiBiase et al.^[3]

In addition, this entry does not review the history of GIS. The reader may consult the extensive discussion in Waters^[1] or in Clarke.^[4] A complete review may be found in Foresman^[5] and comprehensive online resources are maintained with The GIS History Project (<http://www.ncgia.buffalo.edu/gishist/>). Chrisman^[6] has described the transformation of computer mapping software into GIS at the Harvard Laboratory for Computer Graphics and Spatial Analysis during the 1960s and 1970s.

MODERN DEFINITIONS OF GIS

A terse, useful definition of GIS continues to elude the community. Two views of GIS pervade the literature, differing largely because of the difference in the “S” in the acronym. Those scholars that represent the “S” as systems include Clarke,^[4] who provides a number of definitions of GIS. Clarke begins by stating that a GIS is a computer-based system for linking attribute data from a database with spatial information. He notes that a GIS can be described in various ways. Thus some authors have referred to GIS as a toolbox. Similarly, Burrough and McDonnell^[7] state that GIS is a “a powerful set of tools for storing and retrieving at will, transforming and displaying spatial data from the real world for a particular set of purposes.” Longley et al.^[8] review definitions that describe GIS as both data analysis–data display tools and as map-making tools. These definitions emphasize the applied nature of GIS and are generally used by practitioners in the field, such as the government and related industry contractors. These definitions have become more entrenched with the increasing use of software programming packages and languages (e.g., Visual Basic, Python,

and Java, among others) to create sets of procedures that specialized user groups can employ (e.g., transportation planners, see Kang and Scott^[9]).

Alternatively, the “S” in GIS can be taken to represent Science (Mark^[10]). This approach has been advocated by scholars who are actively developing new methods and who view themselves as more than simple toolmakers. Goodchild provides an overview of the differences between GISystems, GIScience and GISudies at <http://www.ncgia.ucsb.edu/giscc/units/u002/u002.html>. According to Goodchild GIScience is the science behind the technology of GIS. It is also the science that keeps GIS at the research frontier. GIScience is thus a multidisciplinary field in which cartography, cognitive psychology, computer science, geodesy, geography, photogrammetry, and spatial statistics are all important contributors.

The tool versus science debate has been reviewed by Wright et al.^[11] It has been resolved largely by the acceptance of both terms and an increased vagueness in the use of the GIS acronym. Within universities this dichotomy is evident in the number of “professional master’s” programs available largely to fill the market for increased application courses and community-based GIS funding in the vein of GISystems. GIScience remains as a realm for continued research and software development, and is popular as a specialization, minor, or additional certificate in degree programs. Academic units with a mix of GIScience and GISystems activity remain healthy.

Finally, Chrisman^[12] has defined GIS as an “organized activity by which people measure and represent geographic phenomena then transform these representations into other forms while interacting with social structures.” This definition reflects the increased interest in the use of GIS for community planning and advocacy. It is such an important new trend that it has been variously referred to as community-based GIS and Public Participation GIS (PPGIS) and more recently as VGIS where the “V” in the acronym indicates volunteer involvement. These developments are described in further detail below.

GIS: THE STATE OF THE ART IN 2008

In 2008, GIS software packages for making maps and for displaying and analyzing spatial data in a variety of ways was commonplace. Large price differences existed, with GIS software packages ranging in cost from free (for GRASS and other open source initiatives) to a few hundred dollars (for Idrisi, MapInfo, and Maptitude) to tens of thousands of dollars (for enterprise versions of TransCAD and ArcServer). These packages generally come with a graphical interface and run on the Windows operating system, although Unix-friendly server editions are becoming common. Mac OS X and Linux are poorly represented, and can only run a subset of existing GIS software without

a Windows emulator or interpreter. Open source software has been particularly successful with these operating systems, to the point that dedicated teams focus on GIS-specific Linux distributions (see information on Debian-GIS at <http://wiki.debian.org/DebianGIS>).

Conducting analysis with GIS software still requires extensive training and this is especially so if it is to be used for decision-making and policy implementation. Most GIS education and training is completed in university undergraduate programs. Post-degree diploma programs are also popular as are graduate level master’s degree programs, and employers frequently pay for such education for their employees.

Web-based GIS applications and the use of software and data online are becoming increasingly common. Many of these Web-based devices are lowering the technical know-how necessary to interact with spatial data. GPS units are capable of calculating driving directions as well as tracking traffic information from a server and rerouting the user on the fly. Cell phones, such as the iPhone, can track their location, navigate users, and check the weather with a few touches of the screen.

Spatial data is still extremely costly in most countries where cost-recovery models are often used by government agencies (see Taylor^[13] for an exhaustive discussion of this topic for various countries around the world). The United States is almost the lone exception to this approach to the provision of spatial data, and it is arguable that this has done much to spawn the world’s most active and innovative GIS industry.

Although GIS, even today, cannot be considered more than a niche application it is now a common place subject in university curricula and is frequently used as a research tool by a large number of university disciplines.^[1] In addition, it is being taught more and more in the K-12 curriculum in schools and is being used in an increasingly extensive number of applications in both the public and private sectors.

Public Participation GIS and Volunteered Geographic Information

During the last decade, GIS has been used more and more for community planning and social advocacy. Such developments have been variously described as Public Participation GIS and Participatory GIS with the acronyms PPGIS and PGIS, respectively, in common use. The most extensive set of resources for participatory GIS may be found at the portal Web site maintained by the integrated approaches to participatory development (IAPAD) organization at <http://www.iapad.org/>. IAPAD maintains a list for those interested in PGIS research and also stores numerous case studies which may be downloaded. In recent years it has promoted as participatory three-dimensional modeling (P3DM) of physical environments

and the ethically responsible use of GIS to protect lands belonging to indigenous communities.

PGIS has now been well accepted by mainstream GIS researchers with highly regarded texts such as that by Craig et al.^[14] devoted to this topic. For a number of years PGIS had its own series of conferences sponsored by the Urban and Regional Information Systems Association (URISA) although during 2006 and 2007 PGIS was again merged into URISA's main, annual conference. The PPGIS Web site (<http://www.ppgis.net/>) maintains an open forum on Participatory GIS and associated technologies.

Volunteered geographic information is an increasingly important and associated development. Software developments that include Google Earth, Google SketchUp, Wikimapia, and OpenStreetMap have allowed citizens with limited or indeed no specialized knowledge of GIS to upload their geographic knowledge to publicly accessible Web sites. This process of "geotagging" and its impact on the future of GIS is discussed by Goodchild.^[15] The Geography Network (<http://www.geographynetwork.com/>) supports project Globe (<http://www.globe.gov/GaN/analyze.html>) which allows students in elementary schools to observe data, for example, the brilliance of the night sky. It is easy for these students to record their observations and upload them to a map where they can become part of a network of thousands of observations from schoolchildren around the world. As Goodchild notes, the children have become geographic sensors.

TEACHING SPATIAL THINKING

GIS Education continues to progress as spatial thinking has received attention at all educational levels. Many vendors of GIS software offer reduced or free versions of their packages for education institutions, and resource materials including data sets and lesson plans are widely available.

Schools

Recently the National Research Council has produced a major study^[16] advocating the teaching of spatial thinking and GIS across the K-12 curriculum. The authors of the report argue that spatial thinking is a constructive mix of three elements: spatial concepts, methods of representation, and spatial reasoning. Indeed the Association of American Geographers has argued recently (<http://aag.org/nclb/nclb.pdf>) for changes to the U.S. No Child Left Behind Legislation that would see an appropriation of funding in this legislation for the teaching of geography and GIS.

It can be argued that GIS should be incorporated into the K-12 curriculum for several reasons. First, it helps with the teaching of geography, a core academic discipline. Major software manufacturers such as ERSI (<http://www.esri.com>)

have made available at no cost software such as ArcGIS Explorer which, at the time of writing is available with seven worldwide coverages that include various themes such as physical relief and political boundaries. Second, spatial thinking is advocated because it helps with other disciplines such as the physical, mathematical and environmental sciences. Third, it prepares students to be better citizens in that the data embedded within a GIS provides them with an understanding of other regions of their country and of other countries within the world. A GIS also prepares them to interact with the world in a more effective manner as an entrepreneur or merely as someone who can use an in-car navigation system more resourcefully.

Evidence to support improved spatial thinking and education in the National Research Council Report is contained in Chapter 4 and Appendix C of the study. Unfortunately, most of this research is dated and will have to be revisited if the council is to succeed in its goal of developing new GIS software that is age appropriate in its design, scope, and sequence.

Information on geographic information technology for teachers and the lay person may be found at http://geography.about.com/od/geographictechnology/Geographic_Technology.htm. A complete set of links summarizing articles, lesson plans, and software for teaching GIS in the K-12 curriculum is available at <http://www.esi.utexas.edu/gk12/lessons.php>.

GIS and geography teaching in elementary and secondary schools has moved forward quickly since 1990. Bednarz and Bednarz^[17] take an optimistic view of the progress that has been made and how future challenges may be addressed. Doering (<http://gis2.esri.com/library/userconf/educ02/pap5039/p5039.htm>) has analyzed the effectiveness of various strategies for teaching about GIS in the K-12 curriculum (see also Doering and Veletsianos^[18]).

Simply put, GIS is a highly effective way of teaching schoolchildren about their world. There is, however, a steep learning curve for teachers and professional development resources constantly need to be upgraded (McClurg and Buss^[19]). Others have argued for a minimal GIS software package that increases in complexity with grade level and focuses on the introduction of geographical concepts appropriate to a child's intellectual development (Marsh et al.^[20]).

Resources for teachers may be found at a link on the ESRI Web site at <http://www.esri.com/industries/k-12/education/teaching.html>. These resources include lesson plans for a variety of ages and skill levels. A list of resources for teachers including annotated bibliographies of the use of GIS in the K-12 system may be found at the Web site <http://gislounge.com/k-12-education-in-gis/>. Links to resources on best practices and "white papers" discussing the future of GIS in school education may be found at this link on the ESRI Web site: http://www.esri.com/library/whitepapers/pdfs/higher_ed.pdf.

The work of the National Center for Geographic Information and Analysis (NCGIA) at the University of California at Santa Barbara in supporting the integration of GIS into the secondary school curriculum may be seen at the following Web site: <http://www.ncgia.ucsb.edu/education/projects/SEP/sep.html>. This Web site also contains links to other sites providing resources and support for K-12 GIS initiatives. Resources for schools in the United Kingdom and a sourcebook that may be ordered online can both be found at http://www.abdn.ac.uk/gis_school/.

A new trend is the linking of qualitative geography to GIS (Mei-Po Kwan^[21]). This development may also unite interest in another new area of research, Children's Geographies (see the new journal of that name and introductory editorial by Matthews^[22]). Children and youths may be used to supply volunteer information that can be incorporated into GIS (see discussion above and Dennis^[23]).

Despite all these developments the reality is that in the year 2008 many schools still do not have the computers or the teacher expertise to take advantage of the resources that are available to them on the Internet. It can only be hoped that this will change in the coming years.

Universities

University education in GIS grew substantially after the introduction of the core curriculum in GIS by the NCGIA in 1990. The original core curriculum was designed to provide university faculty with notes for 75 lectures that represented a year-long introduction to the fundamental issues and concepts in GIS. This curriculum was remarkably successful and about 2000 copies were distributed to over 70 countries after being translated into at least eight languages (including Portuguese, Chinese, Hungarian, Japanese, Korean, Polish, Russian, and French). It may still be found at <http://www.geog.ubc.ca/courses/klink/gis.notes/ncgia/toc.html>.

The new Core Curriculum in GIScience may be found at <http://www.ncgia.ucsb.edu/education/curricula/giscc/> and is still under development. It includes two sets of lecture notes specifically on teaching GIS within a university setting http://www.ncgia.ucsb.edu/education/curricula/giscc/units/u158/u158_f.html. A core curriculum for the closely related field of remote sensing may be found at <http://userpages.umbc.edu/~tbenja1/umbc7/>.

A related occurrence has been the NCGIA's development of CSISS (The Center for Spatially Integrated Social Science <http://www.csiss.org/index.html>).

GIS research and teaching in Universities in the United States has been substantially stimulated through the creation of the University Consortium for Geographic Information Science [UCGIS; (<http://www.ucgis.org/>)]. The UCGIS defines its mission to be "an effective, unified voice for the geographic information science research community." A listing of university-based, GIS courses in the United Kingdom may be found at <http://www.agi.org.uk/> under the Education Link. University based GIS research in the U.K. was also supported by the Regional Research Laboratory initiative.^[1] Canadian GIS degree programs may be accessed at http://www.canadian-universities.net/Universities/Programs/Geography_and_GIS.html.

org.uk/ under the Education Link. University based GIS research in the U.K. was also supported by the Regional Research Laboratory initiative.^[1] Canadian GIS degree programs may be accessed at http://www.canadian-universities.net/Universities/Programs/Geography_and_GIS.html.

Masters courses

In recent years, master's degrees have proliferated at universities in the United States and in many other countries around the world. A listing of these programs, including distance-based offerings, may be found at http://www.ucgis.org/priorities/education/GIS_Cert+Masters_Prog/certificates.htm. Many of these master's degree programs now include modules on programming in GIS. Popular choices for programming languages include Visual Basic, Java, C, C#, and C++ . Students find these courses most attractive and often feel that their education in the GISciences is not complete without some basic training in programming. The more important software vendors such as ESRI (see below) are moving away from their own, proprietary scripting languages toward industry standard languages such as Visual Basic.

In some cases these masters programs have been seen as terminal, professional degree programs which supply a need generated by the GIS industry. Others have seen them as the ideal "springboard" into Ph.D. research in Geography and other disciplines such as Archaeology that use spatially distributed data (see the Web site at http://www.le.ac.uk/geography/postgraduate/msc_gis_hg.html which discusses the Master of Science degree in GIS at the University of Leicester).

Colleges

The NCGIA has developed a core curriculum for technical programs taught in colleges and this may be accessed at <http://www.ncgia.ucsb.edu/education/curricula/ccpt/Welcome.html>. GIS has found a particularly successful niche in technical colleges that offer postgraduate diploma programs. One of the oldest and most successful of these programs has been taught at the College of Geographic Sciences in Nova Scotia, Canada, since the early 1980s. A description of this program may be found at <http://www.cogs.ns.ca/Programs/Geomatics/>. A partial listing of some of the better known college programs in GIS may be found at http://www.ncgia.ucsb.edu/education/curricula/ccpt/resources/example_courses/examples_f.html.

Virtual Campuses

Distance education is a well-established method of instruction in GIS and is sponsored by the UCGIS organization among others. A "white paper" on this topic may be found at (<http://dusk.geo.orst.edu/disted/>). Links to many

U.S. sites that offer distance education may be found at this location together with a link to the UNIGIS International site (<http://www.unigis.org/>) which has offices in 10 separate countries around the world. Perhaps one of the most outstandingly successful attempts at distance education is ESRI's virtual campus which may be found at <http://training.esri.com/gateway/index.cfm?fa=trainingOptions.gateway>. These courses may be either self study or instructor led.

While distance-based education represents an affordable and convenient way of learning about GIS or indeed any other subject it is not without its critics such as Noble.^[24]

SOFTWARE PACKAGES

Software vendors have done much to popularize the use of GIS in academia, government, and industry. This they have achieved by sponsoring software distribution, conferences, Web sites, Web services, and trade newsletters. Here the activities of a number of the more important vendors and software developers are described. Most software vendors now support their own online listserves, Web knowledge banks, and other interactive communities in order to resolve problems for their user base. Information on Open Source GIS software may be found at the Open Source Geospatial Foundation Web site (<http://www.osgeo.org/>) and is discussed in more detail below. A survey of this software undertaken in late 2007 is available at http://www.foss4g2007.org/presentations/view.php?abstract_id=136. The rest of this section lists the leading commercial GIS software.

ESRI

Founded in 1969, ESRI (<http://www.esri.com/>) continues to dominate the industry as the GIS market leader. ESRI offers various configurations of its ArcGIS software. The current version of the ArcGIS software is 9.3 but new releases occur about every 6 months. The Desktop configuration has three components: ArcGIS Desktop, ArcGIS Engine, and ArcGIS Explorer (<http://www.esri.com/products.html#arcgis>). The Desktop product allows for the creation, editing, and analysis of geographic data and the development of professional, publication-quality maps. ESRI provides a server configuration for delivering maps and geographic data across an organization and over the Web. This configuration requires their ArcGIS Server and Image Server products. ESRI's Mobile GIS products include ArcGIS Mobile and ArcPad, products that allow the development of GIS products in the field and full use by clients with mobile devices including phones. ESRI offers data in various formats to populate these GIS products and also as Web services that are available online (<http://www.esri.com/software/arcwebservices/index>

[html](http://www.esri.com/software/arcwebservices/index)). Other organizations that offer Web services include GIS factory (<http://gisfactory.com/webservices.html>) where the services include address finders, district finders, and route finders (http://gisfactory.com/whitepapers/wp_giswebservices.pdf).

ESRI sponsors the ArcWatch e-mail newsletter, the ArcUser magazine, and the ArcNews publication. In 2008 it will hold its 28th annual user conference (<http://www.esri.com/events/uc/index.html>), one of the most popular and enduring of all the yearly GIS conferences. Recently attendance at this premier, vendor-sponsored conference has been around 14,000 attendees. The functionality of the ESRI ArcGIS software has been augmented by a series of extensions that can be deployed to perform specific functions. For ArcGIS these include extensions for analysis, such as Spatial Analyst and Network Analyst, for productivity including, Publisher and Street Map, and solution based software such as Business Analyst and Military Analyst and, finally, Web services. A complete list of ESRI supported extensions may be found at http://www.esri.com/software/arcgis/about/desktop_extensions.html. Extensions developed by their partners may be found at <http://gis.esri.com/partners/partners-user/index.cfm>. A review of these extensions, organized by application type, is provided by Limp,^[25] an article which may be accessed by registering at the GeoPlace Web site (<http://www.geoplace.com>), a GIS industry Web portal. Some extensions are packaged in the form of toolboxes that perform specific GIS operations that are often missing from the standard GIS packages. A prototypical example is Hawth's Tools that provides functionality for a variety of spatial, sampling, and animal movement operations and may be found at the spatial ecology Web site (<http://www.spatial ecology.com/htools/tooldesc.php>).

IDRISI

One of the most popular, affordably priced, GIS products is Idrisi which was developed in 1987 by Ron Eastman and is now supported by Clark Labs at Clark University in Worcester, Massachusetts (<http://www.clarklabs.org/>). Idrisi's roots are as a raster GIS and as such it has been most widely used in resource management, land use change, and image processing applications. At the time of writing, the Andes Edition, the 15th major release, was the current version of this enormously popular GIS software package. The unusual name of the software owes its origins to the famed, twelfth century, Moroccan cartographer, Muhammad al-Idrisi. The Idrisi software is a fully functional GIS and image processing package that is now used in more than 175 countries. It has an especially rich and diverse set of processing modules for analytical research that include the first ever machine learning algorithms for use in a GIS and image processing system, soft classifiers, multi-criteria and multi-objective decision making that provided the first GIS implementation of

Saaty's Analytical Hierarchy Process (Saaty^[26]), sophisticated geospatial statistics, and a dynamic modeling routine that is implemented through a graphical interface.

Intergraph

Intergraph is ESRI's chief competitor for the title of GIS market leader and has been providing GIS and related software for 35 years. Intergraph has a suite of GIS-related products including its GeoMedia products (<http://www.intergraph.com/geomediasuite/>). Intergraph also sponsors its own annual user's conference and publications including the trade publication, *Insight*, which is available online together with Intergraph's e-Connection Newsletter. Intergraph works with business partners such as Hansen Information Technologies (<http://www.hansen.com/>) to provide additional geospatial functionality, in this case for asset management and transportation and related solutions.

MAPINFO

Since 1986 MapInfo Corporation, Troy, New York (<http://www.mapinfo.com/>) has been producing affordable GIS software that is eminently suited to desktop mapping and such applications as geodemographics and target marketing. MapInfo emphasizes location-based intelligence especially in the field of business planning and analysis. It too supports an annual conference, the MapWorld Global User Conference, and provides customer support through online user groups.

Caliper Corporation

Caliper Corporation, Newton, Massachusetts (<http://www.caliper.com/>), produces one of the most sophisticated low-cost GIS desktop mapping products available, Maptitude. This software comes complete with extensive data sets from the U.S. Bureau of the Census and is ideal software for many GIS applications and has been favorably reviewed. A special version of Maptitude is available for building and analyzing political and other redistricting plans. Caliper Corporation's flagship product is TransCAD, a transportation GIS package that has the most complete set of transportation planning and related routines available in any GIS package. The latest release of this software, Version 5, is also produced as a Web mapping package that may be used for developing online transportation planning applications. One suggestion is that this software could be used to do online travel surveys greatly reducing the cost of traditional in-house, paper-based surveys (<http://www.caliper.com/web/gist2002.pdf>). Caliper Corporation is now marketing a GIS-based traffic simulation package, TransModeler.

Autodesk

Autodesk, San Rafael, California (<http://www.autodesk.com>), is the major software developer in the Computer Assisted Drafting market with its AutoCAD product. In recent years it has also added desktop mapping and GIS to its product line with its Map 3D product.

Bentley

In a 2006 study the Daratech organization (<http://www.daratech.com/>) rated Bentley Systems, Inc., as the number two provider of GIS systems worldwide. Their flagship GIS/CAD product, Microstation, was originally developed for Intergraph. It is now available as Bentley Map.

Manifold

Manifold (<http://www.manifold.net/index.shtml>), manufactured by CDA International Ltd., is a low cost GIS that is highly popular with organizations that have limited budgets and lack the technical expertise to work with open source software. It has an online users' support group (<http://forum.manifold.net/forum/>). It is a full featured GIS that in its current release of 8.0 offers 64 bit processing, an Internet map server, and is available in personal and enterprise editions.

Free and Open Source Software

There are numerous GIS packages now available in various amounts of free and open-source packages. GRASS (the geographic resources analysis support system) has made large strides in development since its release under the open source GPL license in 1999 (<http://grass.itc.it/>). It is designed primarily to work on Linux and other operating systems that use X windows (not to be confused with Microsoft Windows).

GeoDA is a specialized analysis tool used to examine spatial autocorrelation and related spatial regression analyses implemented on Windows. PySal (python spatial analysis library) is a shared set of libraries for both GeoDA and the STARS software that is available at the Regional Analysis Laboratory at San Diego State University (<http://regionalanalysislab.org/>).

Software, such as the crime analysis package, Crimestat (<http://www.icpsr.umich.edu/CRIMESTAT/>), are free and used frequently in the professional world, although they are not truly open source. GIS also shares a great deal of overlap with the PostgreSQL and MySQL server backends, and postgis serves as "spatially-enabled" upgrade for PostgreSQL and has been implemented in both the U.S. and U.K. Programs such as terraview (<http://www.terralib.org/>), and mapserver (<http://mapserver.gis.umn.edu/>) have more niche audiences but are also growing in popularity.

Geoexploration Systems

There now exist a number of competing technologies that have been described as geographic exploration systems (Ball^[27]) or geoexploration systems. These technologies include Google Earth, Microsoft's Virtual Earth, NASA WorldWind, and ESRI's ArcGIS Explorer among others. They have become extremely popular since the introduction of "mashup" technology that allows even the neophyte user to combine their spatial data with real world environments across a nation or indeed across the globe. Visualization software such as GeoFusion (<http://www.geofusion.com/>) has been developed to improve download times, allow the integration of multiple data sets, and enhance the interface of these systems. Geoexploration systems have proved extremely useful in aiding the development of participatory GIS where nonspecialists use GIS technology for advocacy planning or to protect the rights of indigenous populations (see discussion above). Volunteer geographic information has been made far more effective by the ease of use of this new type of GIS.

Geographic social networking is a new development that represents the integration of social network technology such as MySpace, video technology such as YouTube, and geoexploration systems like Virtual Earth. This approach is being pioneered by The Carbon Project (<http://www.thecarbonproject.com/>).

SPATIAL AUTOCORRELATION

Spatial analysis continues to be the crux of GIScience's growth. The forms of analysis special to geographic information have continued to be developed and remain unique to the discipline (Gould^[28]). Spatial autocorrelation, the problem of observations near each other having correlated regression residuals, and related analysis has become ubiquitous in the geography literature. Increases in computational resources have allowed for most desktop computers to be able to create weight matrices, calculate spatial autocorrelation, and map significance scores (Anselin;^[29,30] and Anselin and Florax^[31]). These tools were originally implemented in stand-alone software, but are increasingly part of commercial software such as Idrisi and ArcMap.

For more sophisticated forms of analysis, researchers are still forced to use packages such as SpaceStat (<http://www.spacestat.com/>) or the spatial statistics routines in S-Plus (<http://insightful.com>). Modern spatial analysis continues to focus on local models of spatial association (Fotheringham et al.^[32]). These Local Indicators of Spatial Association (LISA) statistics, such as Local Moran's I, are frequent in the literature. Anselin's GeoDA software is the most frequently used software employed to examine these local autocorrelation statistics. GeoDA allows for the creation and analysis of weight matrices, as well as the use of

them to account for spatial autocorrelation in modified regression analysis. Another approach has been to allow the coefficients within regressions to vary over space. This method, termed geographically weighted regression, is promoted by Fotheringham and has received a mixed reception in the literature.

Markup Languages

Markup languages are the *lingua franca* of the Internet. Since its inception hypertext markup language (HTML) has been the dominant method for encoding information for text that is transmitted over the Internet. Essentially HTML does little more than provide a "picture" of a document for the Web user. All markup languages seek to provide information about the data that is transmitted over the Internet. When that data has unique characteristics, as is the case with spatial or geographical data, it requires its own markup language.

Geography markup language has been in development since 1998 and this has been largely due to the efforts of Ron Lake and his company Galdos Systems (<http://www.galdosinc.com/>). GML v3.0 was released as ISO Standard 19136 for the storage and transport of geographic data. GML is now the standard for the GeoWeb (<http://www.geoweb.org/>). It thus allows devices that are connected to the Internet to store and transmit geographical data across the Internet permitting the efficient use of Web services. Like XML, it has also spawned other related markup languages including CityGML which enables the storage and exchange of three dimensional objects that describe urban infrastructure (<http://www.citygml.org/>). In late 2007, CityGML was officially adopted by the Open Geospatial Consortium as the preferred markup language for urban infrastructure.

More commonly, GIS data on a server is accessed through flash and JavaScript applets that do not require the screen to refresh every time the user makes a change but instead the onscreen image will change "on the fly." This has vastly increased the usability of many online GIS applications. However, it also has made it far more difficult to create these GIS systems, with more advanced training required for these software and database packages.

GIS AND ITS APPLICATIONS

A major strength of GIS has been its ability to prove itself useful in a great many application areas. The reader may find detailed discussions of the use of GIS in the management of utilities, telecommunications, emergency management, land administration, urban planning, military applications, library management, health care, political redistricting, geodemographics and target marketing, agriculture and environmental monitoring in Longley et al.^[8]

Each of these application areas has an extensive literature of its own and these are described in the various chapters included in Longley et al.'s comprehensive review of the discipline.

CERTIFICATION OF GIS PROFESSIONALS

An ongoing concern for GIS professionals has been the need for certification. Many individuals and organizations have argued that GIS professionals should be certified in a manner similar to the certification of engineers, geologists, psychologists, and others in professional disciplines. In 1998 the Urban and Regional Information Systems Association (URISA: <http://www.urisa.org/>) created a Certification Committee. After extensive industry-wide debate, the finalized portfolio-based certification program was established in 2003. This certification process was adopted and administered by the newly established GIS Certification Institute (<http://www.gisci.org/>). Certification involves establishing evidence of professional competence and ethical conduct. Until January 1, 2009, a "grandfathering" process was also permitted. At the end of 2007 almost 2000 individuals have availed themselves of the certification process.

GIS AND THE FUTURE

Judging the future of the discipline is difficult, as rapid advancements make such statements outdated by the time of publishing. Such is the case in a recent work by Reuter and Zipf (<http://www.i3mainz.fh-mainz.de/publicat/zipf05/gis.where.next-reuter-zipf.pdf>), that predicts the trajectory of a device to support trip planning that is partially implemented in a new release of the iPhone. As GIS presses onward, it will continue to be embedded within more and more electronics. While appliances such as refrigerators and stoves do not generally need location information, most devices that move today already have some sort of location-finding mechanism inside them. The future of these devices may rely on the ability to more precisely locate themselves, particularly inside buildings. Reuter and Zipf suggest this may come in a ground-based GPS system they term a "Global Universal Computer."

The amount of spatial data is blossoming and will likely continue to do so. As users mark important personal events and places linked to particular places, storage and retrieval of this data will become increasingly important. Reuter and Zipf suggest it is the storage and search of these items that will be most important. This technology may be crucial to historians and psychologists working to understand the reasons for individual behavior.

At some point, the lack of widespread spatial education will segment the population further, based on those who can use new integrated devices and those who cannot.

Technological advances will make up for some of this digital divide by simplifying interfaces. However, these new interfaces generally cannot wholly account for such differences and maintain full functionality without a significant paradigm shift.

Finally, it may be noted that GIS in the future will become more involved with the third and fourth dimensions. The third dimension is already being implemented in geographic exploration systems and the integration of products such as Google SketchUp (<http://sketchup.google.com/>) into Google Earth. The fourth dimension is time, a difficult concept to incorporate into traditional GIS software structures. Peuquet^[33] has provided part of the theoretical paradigm for this new implementation and new versions of commercial software such as ESRI's ArcGIS 9.3 make it easier to create animated visualizations of geodatabases. 3-D/4-D GIS will be the new frontier.

BIBLIOGRAPHY AND ADDITIONAL RELATED RESOURCES

GIS Day

On November 14, 2007, GIS Day was held in over 80 countries around the World and in all 50 states in the United States. GIS Day is a grassroots movement in which GIS users and vendors (academics, government employees and entrepreneurs) open their doors to schoolchildren and all members of the general public in order to showcase the capabilities of GIS projects which they have developed (<http://www.gisday.com/>). The event is sponsored principally by the National Geographic Society, the Association of American Geographers, the University Consortium for Geographic Information Science, the United States Geological Survey, The Library of Congress, Sun Microsystems and Hewlett-Packard and ESRI, and by local GIS organizations. The next GIS Day will be held on November 18 and 17 in 2009 and 2010, respectively. The event is usually held as part of Geography Awareness Week, which has been sponsored by the National Geographic Society since 1987. The U.S. e-Government Web site using data from Daratech estimates that there are 1,000,000 users of GIS worldwide, half of whom are in the United States (<http://www.whitehouse.gov/omb/egov/c-7-10-b-geospatial.html>).

Books

The most important reference works for GIS are the so-called "Big-Books" of GIS. The first edition of this huge, two-volume review of the state of the art in GIS was edited by Maguire, Goodchild, and Rhind^[34] and published in 1991, while the second edition was edited by Longley, Goodchild, Maguire, and Rhind^[35] in 1999.

More recently, the second volume has been published in a paperback edition with editorial updates based on input from the individual chapter authors, various additional chapters, and a CD featuring all the chapters from the second edition (Longley et al.^[36]). Popular textbooks discussing the concepts behind GIS include Longley et al.^[37] and Clarke.^[4] The latter author provides an extensive list of GIS books magazines and journals, conference proceedings, and professional organizations. Price's^[38] text is a guide to operating the industry leading ArcGIS 9.2 software and includes a series of hands-on tutorials to aid the novice user.

A searchable GIS bibliography may be found at ESRI's Web site: <http://training.esri.com/campus/library/index.cfm>. Important publishers of GIS texts include ESRI (http://store.esri.com/esri/category.cfm?SID=2&Category_ID=35) and Taylor & Francis (<http://gis.tandf.co.uk/>). Longley et al.^[37] provide a list of major GIS textbooks while Chrisman^[6] describes the earliest days of the discipline. Vendor publications have been discussed above. Suffice it to note that most major vendors have a company publication designed to inform their user base of the latest developments in their software products and many of these are now available online.

Journals and Magazines

Some of the main academic journals in which GIS research is published include

Annals of the Association of American Geographers (<http://www.aag.org/>);
 Canadian Geographer (<http://www.blackwellpublishing.com/CG/>);
 Cartographica (<http://www.utpjournals.com/carto/carto.html>);
 Cartographic Perspectives (<http://www.nacis.org/index.cfm?x=5>);
 Cartography and GIS (<http://www.cartogis.org/>);
 Computers, Environment, and Urban Systems (<http://www.elsevier.com/locate/compenvurbsys>);
 Computers and Geosciences (<http://www.elsevier.com/locate/cageo>);
 Conference Papers in GIS (<http://srmwww.gov.bc.ca/gis/papers/index.html>);
 ESRI User Conference Proceedings (<http://gis.esri.com/library/userconf/index.html>);
 Geocarto International (<http://www.geocarto.com/geocarto.html>);
 Geographical Systems (<http://link.springer.de/link/service/journals/10109/>);
 GeoInformatica (<http://www.wkap.nl/journalhome.htm/1384-6175>);
 Geoscience E-Journals (<http://paleopolis.rediris.es/geosciences/>);

Geographical Journal (<http://www.ingentaconnect.com/content/bpl/geoj/latest>);
 GeoJournal (<http://www.ingentaconnect.com/content/klu/gejo/latest>);
 GIS Law;
 IEEE Transactions on Computer Graphics and Applications (<http://ieeexplore.ieee.org/xpl/RecentIssue.jsp?punumber=38>);
 IEEE Transactions on Geoscience and Remote Sensing (<http://ieeexplore.ieee.org/xpl/RecentIssue.jsp?punumber=36>);
 International Journal of Geographical Information Science (<http://www.tandf.co.uk/journals/titles/13658816.asp>);
 International Journal of Remote Sensing (<http://www.tandf.co.uk/journals/frame/loader.html?http://www.tandf.co.uk/journals/tf/01431161.html>);
 International Journal of Mapping Sciences and Remote Sensing (<http://www.ingentaconnect.com/content/bell/msrs/latest>);
 Journal of Geographical Systems (<http://link.springer.de/link/service/journals/10109/index.htm>);
 Photogrammetric Engineering and Remote Sensing (<http://www.asprs.org/publications/pers/www.asprs.org/publications/pers/>);
 Public Health GIS News and Information (http://www.cdc.gov/nchs/about/otheract/gis/gis_publichealthinfo.htm);
 Remote Sensing Reviews (<http://www.tandf.co.uk/journals/online/0275-7257.asp>);
 Transactions in GIS (<http://www.blackwellpublishing.com/journals/tgis/>);
 The Spatial Odyssey Website also has a list of GIS Journal Abstracts and Citations (<http://libraries.maine.edu/Spatial/gisweb/journals/journals.html>).

Many **magazines** are available in both an online and a paper version. Some of the more notable examples are

ArcNews Online (<http://www.esri.com/news/arcnews/arcnews.html>);
 ArcUser Online (<http://www.esri.com/news/arcuser/index.html>);
 Challenges: A news letter from UCGIS (<http://dusk2.geo.orst.edu/ucgis/news/>);
 Asian surveying and mapping (<http://www.asmmag.com/>);
 GEOWorld (<http://www.geoplace.com/>).

Other online GIS-oriented magazines include

Directions Magazine (<http://www.directionsmag.com/>);
 Earth Observing Magazine (<http://www.eomonline.com/>);
 GeoCommunity (<http://www.geocomm.com/>);

Geomatics Information and Trading Centre (<http://www.gitc.nl/>);
 GeoSpatial Solutions (<http://www.geospatial-online.com/>);
 GeoVision (<http://www.gisvisionmag.com/>);
 Geomatics Info Magazine International (<http://www.reedbusiness-geo.nl/Home.asp>);
 GPS World (<http://www.gpsworld.com/>);
 Spatial News (<http://spatialnews.geocomm.com/>);
 Mentor Software (<http://www.mentorsoftwareinc.com/cc/ccdir.htm>);
 Position Magazine (<http://www.positionmag.com.au/>);
 Professional Surveyor Magazine Online (<http://www.profsurv.com/>);
 The CADD/GIS Technology Center CADD/GIS Bulletins Page (<https://tsc.wes.army.mil/news/bulletins/>).

Organizations

The following are some of the better known organizations with a strong interest in GIS:

The American Congress on Surveying and Mapping (ACSM) (<http://www.acsm.net/>);
 The American Society for Photogrammetry and Remote Sensing (ASPRS) (<http://www.asprs.org/>);
 The Association for Geographic Information (AGI) (<http://www.agi.org.uk/>);
 The Association of American Geographers (AAG) (<http://www.aag.org/> this organization has a specialty group devoted to GIS) (<http://geography.sdsu.edu/aaggis/>);
 The International Geographical Union which has a Commission on Geographical Information Science (<http://www.hku.hk/cupem/igugisc/>);
 The North American Cartographic Information Society (NACIS) (<http://www.nacis.org/>);
 Geospatial Information and technology Association (<http://www.gita.org/>);
 The Urban and Regional Information Systems Association (URISA) (<http://www.urisa.org/>).

Conferences

This section lists a number of the more important conferences other than the vendor-specific conferences mentioned above. Many of the general, omnibus GIS Conferences have in recent years folded as more specialized offerings take their place. These conferences have usually produced either a print proceedings or a proceedings on CD-ROM.

Most of the major GIS organizations such as URISA will also have annual and even regional GIS conferences. Some conferences are strictly devoted to a single theme and are strongly oriented toward training. This is true of

the Web mapping conferences (<http://www.gisconferences.com/>). In 2007, the following was a selection of the conferences held across the globe:

ACM GIS conference in Bellevue, Washington
 Africa GIS conference in Ouagadougou, Burkina Faso
 AGIC (Arizona Geographic Information Council); GIS conference in Prescott, Arizona
 AGILE (Association Geographic Information Laboratories Europe); conference on GIS in Aalborg, Denmark
 Annual CA Geographic Information Association conference in Cypress, California
 Annual GIS conference, ASPRS and URISA in Vancouver, Washington
 Annual GIS for Oil & Gas Conference in Aurora, Colorado
 Annual International airport GIS conference in Budapest, Hungary
 Annual Minnesota GIS conference in Rochester, Minnesota
 Annual Missouri GIS conference in Osage Beach, Missouri
 Annual NC GIS conference in Winston-Salem, North Carolina
 Annual Ohio GIS conference in Columbus, Ohio
 Annual Virginia GIS conference in Virginia Beach, Virginia
 Arc GIS conference in Biloxi, Mississippi
 Biennial GIS conference, Iowa Geographic Council in Sioux City, Iowa
 California GIS conference in Oakland, California
 Croatian GIS Association conference in Sinj, Croatia
 Delaware GIS conference in Dover, Delaware
 East Tennessee GIS conference in Pigeon Forge, Tennessee
 Eastern Montana GIS conference in Miles City, Missouri
 ESRI Asia-Pacific User Conference in New Delhi, India
 ESRI Australia: GIS user conference in Sydney, Australia
 ESRI Eastern Africa: GIS user conference in Kampala, Uganda
 ESRI Federal Users GIS conference in Washington, District of Columbia
 ESRI GIS solution expo in Danvers, Massachusetts
 ESRI Health GIS conference in Scottsdale, Arizona
 ESRI International User conference in San Diego, California
 ESRI New Zealand: GIS user conference in New Zealand
 ESRI South Asia user conference in Novotel Clarke Quay, Singapore
 EUC (European User Conference) in Stockholm, Sweden

The GeoTec Event in Ottawa, Ontario, Canada
 GI and GIS conference in Porto, Portugal
 GIS conference, Office of Lt Governor, U.S. Virgin Islands
 GIS Engineers Society conference in Trivandrum, India
 GIS for public sector conference in London, U.K.
 GIS for Urban Environmental summit in Johannesburg, South Africa
 GIS in Rockies conference in Denver, Colorado
 GIS in Transit in Tampa, Florida
 GIS South Africa conference in Umhlanga Rocks, Durban
 Historical GIS conference in Nagoya, Japan
 Homeland Security GIS summit in Denver, Colorado
 Illinois GIS conference (ILGISA) in Oak Brook, Illinois
 Indiana GIS conference in Indianapolis, Indiana
 Indonesian Geospatial Technology Exhibition in Jakarta, Indonesia
 Intermountain GIS conference in Donnelly, Idaho
 International conference of GIS/RS in Hydrology in Guangzhou, China
 International conference on Health GIS in Bangkok, Thailand
 International GIS crime mapping conference in Brussels, Belgium
 Ireland GIS conference in Dublin, Ireland
 Kentucky GIS conference in Louisville, Kentucky
 Kuwait GIS conference in Kuwait
 Map Asia in Kulamanpur, Malaysia
 Memphis Area Geographic Information Council GIS conference in Memphis, Tennessee
 National GIS symposium in Saudi Arabia in Khobar, Saudi Arabia
 Nebraska GIS Symposium in Omaha, Nebraska
 Nordic GIS conference in Herning, Denmark
 North Dakota GIS user conference in Bismarck, North Dakota
 North Western PA GIS conference in Clarion, Pennsylvania
 Northeast Arc Users Group: GIS conference in Burlington, Vermont
 NSGIC (National States Geographic Information Council); in Madison, Wisconsin
 NYS GIS conference in Liverpool, New York
 PA GIS conference in Harrisburg, Pennsylvania
 Pacific Islands GIS/RS conference in Suva, Fiji
 Real estate GIS user conference in Scottsdale, Arizona
 Rhode Island GIS conference in Narragansett, Rhode Island
 ScanGIS—Scandinavian GIS Conference in As, Norway
 Southern Forestry and Natural Resources Management GIS conferences in Kissimmee, Florida
 Super map GIS conference in Beijing, China

Towson GIS conference in Towson, Maryland
 UGIC (Utah Geographic Information Council)—GIS conference in Salt Lake City, Utah
 URISA & IAAO 11th Annual GIS conference in Las Vegas, Nevada
 URISA (urban regional information systems association)
 VIGIC (Virgin Islands Geospatial Information Council)
 Washington GIS conference in Lynnwood, Washington

GIS Dictionaries

The Association for Geographic Information has an online dictionary at <http://www.geo.ed.ac.uk/agidict/welcome.html>. For a published GIS dictionary McDonnell and Kemp's^[39] International GIS Dictionary can be referred to.

ACKNOWLEDGMENT

The authors would like to thank Matt Ball for comments on an earlier draft.

Geographical Literature: History [ELIS Classic]

Nora T. Corley

Arctic Institute of North America, Montreal, Quebec, Canada

Abstract

One of the objectives of the information disciplines is to study the universe of recorded information—that is, to study the documentary products of domains of human activity—and to come to understand such bodies of literature as social and historical phenomena in and of themselves. Corley traces the development of the discipline of geography in parallel to the development of the literature of geography.

—*ELIS Classic*, from 1973

INTRODUCTION

Geography is, by definition, the science that describes the surface of the earth: the land, the sea, the air, the distribution of animals and plants, man and his works, and the relationships of all of these elements. The word “geography” itself is derived from Greek words meaning “earth description.”

Like other academic disciplines, geography has its own body of literature and its own peculiar ways of looking at the problems under investigation. As a science, geography dates back to antiquity, in fact, it is perhaps the oldest science of all. But scientific geography as we know it today dates back only to the end of the eighteenth century, when Kant, Humboldt, Peschel, Ratzel, and others defined the scope and content of geography, and dictated the methods of collecting, organizing, and presenting the material.

HISTORY

Primitive man has always been a keen observer of his own country and any he traveled through (even today Eskimos can give an extremely detailed description of an area that to the untrained and unfamiliar eye might otherwise be called featureless).

Geography was held in great esteem by the ancient Greeks, who traveled and accumulated facts, charted and mapped their world, and speculated about the knowledge they had gathered. The information they collected was of prime importance to their merchants, administrators, statesmen, and military.

Thales of Miletus (624–546 B.C.), thought to be one of the most talented men of all time, was one of the earliest geographers. In fact he founded Greek mathematics, astronomy, and physics, as well as geography. Thales realized that the surface of the earth was curved because of the different slant of the sun as one traveled north. He also noted that the slant of the sun’s rays changed with the

seasons, and he invented the equator and the plane of the ecliptic. He also suggested that the earth could be divided by circles parallel to the equator and lines perpendicular to it, now known as lines of latitude and longitude.

Hecataeus (fl. 500 B.C.), sometimes called the father of geography, wrote about his travels to Egypt, Persia, Libya, Spain, and Italy; unfortunately only fragments of his narrative are extant. He considered the earth a flat disk surrounded by a river of ocean. His works were the first regional geography. His map was an extension of one made by Anaxemander who, along with Thales, Aristotle, and Eratosthenes, developed mathematical geography. They proved the earth to be a sphere; computed its size fairly accurately; established the latitude and longitude of many places; and began the practice of plotting maps on grids.

Homer, too, is sometimes referred to as the father of geography, as much of his poetry dealt with the geographical lore of the day, gleaned from the tales of ancient travelers.

A third claimant to this same title was Herodotus (ca. 485–428 B.C.), who was the first to designate Europe, Asia, and Africa as three distinct continents. Herodotus had traveled widely throughout the Near and Middle East, seeking out and questioning the intellectuals in each locality. He did not ascribe to the theory of a disk-shaped earth rimmed by a river of ocean. Instead he gave a detailed description of the world as he knew it as far east as India, west to the Pillars of Hercules, north to the forest boundary of the steppes, and south to the present Sudan. His work is distinguished by the excellent descriptions of town sites.

Theophrastes (ca. 370 B.C.) was the first to note the relationship between plants and climate, and so began the study of plant geography.

Eratosthenes (ca. 276–194 B.C.) was the curator of Ptolemy II’s library in Alexandria, which contained some 40,000 books. He was reputed to be the most learned man of antiquity. His *Geographica* described the world as he knew it, summarizing the history and concepts of

geography. He is credited with naming the subject, though he certainly did not invent it. Eratosthenes also calculated the circumference of the earth at 250,000 stadia (approximately 25,000 miles), coming very close to the actual figure.

Pomponius Mela (ca. A.D. 50) employed the concept of a world symmetrically divided into four by two narrow strips of ocean, despite the fact that realistic geographies had been written based on explorers' and travelers' reports. In his textbook, written in Latin (which made it influential in medieval times), he maintained that the unknown parts of the continents were not necessarily inhabited by people, and that those who lived at the "bottom" of the world were foot to foot with those at the "top," and so he called the former Antipodes (a term no longer used for a people, but rather for a place).

The Romans were not scientifically minded and so added little to geographic thought. Rather, they were concerned with more practical things such as the problems of commerce, administration, and military conquest. They did, however, contribute the *itinerarii* which were descriptions of their road systems—a kind of map, without scale or projection. They were designed only as a convenience to travelers.

Strabo (63 B.C.—A.D. 36) was a Greek regional geographer living in Rome. He summarized (in 17 volumes) the geographical knowledge of his time in his *Geographica*, which has survived.^[1] Strabo relied heavily on other Greek authorities, but maintained that it was the geographer's task to describe the known world, to write about the different countries, and to discuss the differences between them. He used the reports of travelers and merchants, seamen's handbooks, and histories of Alexander's conquests as well as material relative to the Roman empire and its trade routes. Strabo's treatment of regional geography at the turn of the millennium is the most elaborate to survive. Since it was written in Greek and was not translated until a long time after, it did not have the influence that it deserved.

Ptolemy (Claudius Ptolemaeus) taught and studied in Alexandria from A.D. 127–151. His great general work *Geographike Syntaxis* dealt with map projections, included tables for latitude and longitude, and gave calculations for the length of day and night for various places depending on their distance from the equator. This work was far beyond the standard of its predecessors. It was translated into Arabic in A.D. 815 and much later (A.D. 1475) into Latin, thus becoming both a Christian and a Moslem authority.

Ptolemy considered *geography* as the description on mathematical principles of the whole world, *chorography* as a detailed account of a region, and *topography* as a minute account of a smaller area. The world, according to Ptolemy, stretched from Spain to China, and from Thule to south of the equator.

During the Middle Ages geography as a science almost disappeared. It was forbidden by the Christian Church as a

pagan science; the theory of the spherical shape of the earth was denounced and the accepted concept was that of a flat disk with Jerusalem at the center. However, at this time geography was being encouraged by the Arabs. Their empire extended, at its height, over most of Europe, Asia, and Africa. In the eastern Mediterranean they came into contact with Greek learning and libraries. Because of Ptolemy's work, descriptive geography flourished. The continued existence of the Roman roads and the compulsory pilgrimages to Mecca encouraged people to travel throughout the empire, and so trade arose as a natural result; all of which influenced geography. The Arabs made accurate calculations of latitude and longitude and the size of the earth, but they made no improvement in the science of cartography. Arab maps were often distorted because of their love of flourish and ornamentation. However, their sea charts, which were based on a cylindrical projection, were highly thought of by the explorer Vasco da Gama. Regional geographical handbooks were written for travelers, merchants, and administrators by ibn Haukal, Masudi, and Idrisi. These were not translated and so had no influence in the West.

Because of the relatively easy travel throughout the Arab empire, it was possible for Marco Polo (1254–1324) to travel overland to China. His account of his journey, and his return by sea has been a widely read story since it was first published. *The Book of Marco Polo* (1296–1299) is an attempt at systematic geography. He was not writing from his own observation in every chapter, but assembled the best information that was available to him. This is particularly true of his chapter on the Indian Ocean. His adventures stimulated exploration in the Christian world, and though written in the thirteenth century, at the end of the next century it supplied Columbus with considerable support to his theories.

About 1357 the spurious *Travels* of Sir John Mandeville (ca. 1300–1372) were published and, thought to be authentic, they were very popular. The book was based on real travelers' tales and tall stories, as well as on Pliny and Solinus. The author also noted the spherical shape of the earth.

Beginnings of Modern Geography

Explorers

Modern geography began when man became aware of the fact that there were lands still to be discovered. Numerous people went exploring—found new worlds, circumnavigated the earth, and returned home with detailed observations and maps of what they had seen. They were exercising a modern geographer's technique—that of gathering data in the field. Their notes were used by contemporary writers of books and compilers of atlases.

About 1418 Henry the Navigator (1394–1460) established a school of geographers. Though he did not travel

himself, Henry sent out many exploring expeditions, notably Vasco da Gama's in 1498 which opened the way to the Indies via the Cape of Good Hope. About the same time Columbus discovered America, and so did Cabot. Vespucci discovered South America and in 1520–1521 Magellan sailed completely around the world, proving for once and for all the sphericity of the earth and the continuity of the oceans. The narratives of these great explorations took an important place in the literature of geography during the great age of discovery.

Editions of Ptolemy's works continued to appear, enlarged with new tables. Sebastian Münster's (1489–1552) *Cosmographia universalis*,^[2] a political and regional work based on Strabo, was the most complete attempt to rewrite the classics, and was most popular.

In 1570 Abraham Ortelius (1527–1598) published his *Theatrum Orbis Terrarum*^[3] of regional and world maps. This was the first modern atlas. A few years before (1598) his friend Gerhard Kremer, better known as Mercator (1512–1594), had published his famous map projection, now known as the Mercator projection, for use in navigation.

Philipp Clüver (1580–1622), a German, published an *Introduction to Universal Geography*.^[4] This was a brief account of mathematical geography, with regional descriptions of the world. It was an excellent work, and set a standard for regional geography that was long unsurpassed.

By 1642, when the Dutch mariner Abel Tasman (1602 or 1603–1659) completed the delineation of Australia, the land masses of the world, except for the Antarctic, were fairly well known. The next 150 years saw further exploration.

Writers

Another Dutchman, Varenius (Bernhard Varen, 1622–ca. 1650) published in 1650 the most notable geographical textbook of the time: *Geographia Generalis*.^[5] This was the first book to include the new theory of the universe as set forth by Copernicus, Kepler, and Galileo. Varenius defined geography as a branch of mathematics, not wanting to limit it merely to the regional descriptions of countries. He included human geography only as a concession to custom. In 1672 his book was reprinted in London at the insistence of Sir Isaac Newton, who wished to have it as a text for his students at Cambridge. It was translated into English in 1732, but Varenius was considered a very difficult writer, and though his book, unfinished because of his early demise, was not expected to be read outside the universities, it was for centuries considered a standard text.

The English geographer Nathaniel Carpenter (fl. early seventeenth century) had some years before delineated geography in two books.^[6] His methods and sources were similar to Varenius's, and he came to the same conclusions. Many of Carpenter's themes were drawn from the French

political theorist Jean Bodin—especially in dividing the world into three climatic zones: torrid, temperate, and frigid; and attributing to the inhabitants of each region certain general characteristics. Carpenter was dogmatic on this aspect—men in colder climates were strong, tall and active; those of the warmer regions were languid; also people living in mountains or highlands were superior to those of the plains. He deemed Europe the most favored region in the world.

For a century after Varenius there was little geographical research; most interest was in the natural sciences. However, the unprecedented expansion of knowledge in these fields made it possible to give a more scientific description of the earth. By the early eighteenth century geography was taking its place as an independent science.

Geography as a Science

Though Jean Jacques Rousseau (1712–1779) was not a geographer, he made many interesting geographical observations. He noted that environment exercised influence on primitive man; the varieties of soils, climates, and the seasons introduced differences in their manner of living. He accepted these differences between northerners and southerners without going into the matter to any degree. He was apt to select unique instances to support his geographical arguments. He realized that the relationship between geography and history was not as simple as generally supposed.

Anton Friedrich Büsching (1724–1793) in his *Neue Erdbeschreibung*^[7] described the surface of the earth, being as accurate as possible, without trying to explain facts or relationships. A regional description was made by political units, and he insisted on a very high standard of accuracy and on the critical handling of his sources. Büsching opened a new era in the science of geography—for the next 150 years, up until the beginning of the twentieth century, geography became almost solely a German science, and the significant developments were made by German scholars.

Next came Johann Rheinhold Forster (1729–1798), and his son, Johann Georg. The elder Forster had a keen scientific mind and great powers of observation. He collected facts, classified them and compared them, made generalizations, and sought explanations. His works were noted also for their contribution to human geography. He was one of the first to try to explain the relationship between man and his environment.

Johann Georg Forster (1754–1779) was not as gifted as his father but, as is often the case, he was more honored in his lifetime. He translated his father's famous *Observations* (1778);^[8] he was a friend of Humboldt, who had been stimulated by the younger Forster's *Voyage around the world* (1777)^[9] (based on the elder Forster's travels), and by whom he was often quoted.

The philosopher Emmanuel Kant (1729–1804) stressed physical geography in his lectures and writings, and he recognized its position in relation to the other natural sciences.

The nineteenth century saw the exploration of the interiors of the continents. The journals and diaries subsequently published by the explorers were an important contribution to regional geography, and later to historical geography. They described the country as they saw it, and in most cases, as it is no longer. In Canada there were Samuel Hearne, Sir Alexander Mackenzie, David Thompson, and Sir John Franklin; and later Sir John M'Clure, Sir Edward Parry, and others opened up the Canadian Arctic searching for Franklin's lost expedition. In the United States there were explorers such as Merriweather Lewis and William Clark, Zebulon Pike, Stephen Harriman Long, Benjamin Bonneville, and John C. Fremont.

In Africa there were such men as Mungo Park, David Livingstone, Stanley, Sir Richard Francis Burton, and John Hanning. In India Sir Francis Younghusband, Evariste Régis Huc, and Nikolai Przhevalsky. Sven Hedig and Sir Aurel Stein visited the interior of the Asian continent, and Ferdinand Baron von Richthofen made seven journeys into China. In Australia there was Captain Charles Sturt, Thomas Mitchell, Dr. Ludevig Leichhardt, Robert O'Hara Burke, and William John Wills.

The Antarctic continent did not come in for intensive exploration until the twentieth century, when Robert Falcon Scott and Sir Douglas Mawson and others made their mark. At the beginning of the twentieth century the Arctic also contributed some famous explorers: Robert E. Peary, Frederick Cook, Knud Rasmussen, Roald Amundsen, Fridtjof Nansen, Vilhjalmur Stefansson, and Otto Nordenskiöld.

MODERN GEOGRAPHY

It is generally agreed that modern geography was founded by two German masters of the subject: Alexander von Humboldt (1769–1859) and Karl Ritter (1779–1859). Humboldt was a great scientist and traveler. He traveled extensively throughout Latin America and Asia gathering data, mapping and sketching in the field, and returned home to write up his results. Ritter, on the other hand, was a historian who carefully considered and cataloged other researchers' data. Though these two scholars approached geography from different backgrounds, they both made such a significant contribution to the subject that the course they charted for the science of geography is still largely followed today.

Humboldt made his first foreign tour with J.R. Forster, whose methods of careful observation and treatment of facts, as well as his scientific description of landscapes, greatly impressed him. Humboldt spent five years in Latin American and the next 20 writing up his notes. His *Ansichten der Natur*,^[10] written when he returned from

Mexico in 1808, gave a suggestion of a pattern of regularity on the earth's surface and received widespread attention. In 1829 he went to the Urals to study the ore-bearing regions, and eventually ended his career as chamberlain to the King of Germany.

Humboldt's *Kosmos*,^[11] published in five volumes, was a comprehensive survey of the universe. His was an empirical approach to research. He combined geography and astronomy in a classical fashion, but kept to the principle of the unity of nature.

Karl Ritter spent 20 years as tutor in a rich family and the rest of his life teaching (he was professor of geography at the University of Berlin), writing, and directing the Gesellschaft für Erdekunde. His great work was his *Die Erdkunde, im Verhältnis zur Natur und zur Geschichte des Menschen, oder Allgemeine, Vergleichende Geographie*,^[12] a comparative regional geography of the world. It was never finished although 21 volumes were published on Asia and Africa. Ritter's approach, like Humboldt's, was empirical. He stressed comparison of phenomena in various regions rather than drawing conclusions from only one. His rule was to proceed from observation to observation and not from hypothesis or opinion to observation. Ritter's literary style was very difficult, often lacking clarity or precision of expression, and so he is frequently misunderstood. Though his books are today considered to be unreadable, his position as a father of geography has been established on the basis of the whole of his writings, and not on any one particular work.

The writings of the two great men were complementary. Humboldt gave method and form to systematic geography; Ritter founded regional geography. Unfortunately, they left no followers. Humboldt never taught, and Ritter's vacated chair was never filled. In their wake they left confusion and shifting points of view. Physical geography was stressed; there was a desire that it be considered a natural science. Human geography, thought to be unscientific, was treated only when necessary to the description of various regions.

One of the most notable geographical works of the nineteenth century was the *Physical Geography* (1848)^[13] by Mary Somerville (1780–1872). This book showed an interest in historical geography and a concern for its basic physical foundations, thus anticipating two popular trends of the twentieth century.

Arnold Henry Guyot (1807–1884), a Swiss and a follower of Ritter's, wrote *The Earth and Man*,^[14] which was translated into English in 1849. This book helped introduce German ideas to English-speaking geographers. Guyot set forth some of geography's significant problems and so helped define the limits of the new science. As professor of geography at Princeton he contributed to the advance of physical geography, stressing the study of structure, surface formations, and erosional processes.

Ritter's most successful pupil was Jean Jacques Elisée Reclus (1830–1905) whose *La Terre* (1867–1868)^[15] was

a systematic study in physical geography. His 19 volume *Nouvelle Géographie Universelle* (1875–1894)^[16] was another complete regional geography of the world. This work shows a wide knowledge and understanding of contemporary advances in the natural sciences, and it also demonstrates a deep appreciation of natural beauty.

Pièrre Guillaume Frédéric LePlay (1806–1822) studied environmental influences on man in urban and rural areas, and so laid the foundations for regional surveys such as town and country planning. His *Ouvriers Européens* (1855)^[17] in six volumes was based on carefully collected data, such as family budgets, a method that has since been used in many economic surveys.

Oscar Peschel (1826–1875) revolutionized morphological research. His work, systematic and empirical, tended to produce geomorphologists and climatologists first, and geographers second [*Neue Probleme der Vergleichende Erdkunde als Versuch einer Morphologie der Erdoberfläche* (1870)^[18]].

Friedrich Ratzel (1844–1904) developed systematic and scientific human geography, though he also made contributions to physical geography, geology, zoology, and ethnology. His *Anthropogeographie* (1882),^[19] a word he coined, attempted to show in the first volume that man's distribution on earth was more or less controlled by nature. In the second volume he described man's existing distribution, going over Ritter's ground and developing his ideas. However, Ratzel's work differed from Ritter's in that he treated human geography regionally rather than systematically. His *Politische Geographie* (1897),^[20] another term he coined, reshaped an old subject. Ritter's last great work *Die Erde und das Leben* (1901–1902)^[21] sought to discuss the earth as an integral whole.

Baron Ferdinand von Richthofen (1833–1905) taught geography at Leipzig, where he stressed a unified geography based on the concepts of Humboldt and Ritter. Trained as a geologist, he developed scientific morphology in his studies of the loess regions of China. His *China. Ergebnisse eigener Reisen und darauf gegründeter Studien*^[22] appeared in five volumes, partly posthumously, from 1877–1912, and set the seal on his reputation. A master of observation in the field, his first two volumes were immediately recognized as a great scientific work, and for them he received the Royal Geographical Society's Founders Medal. For many years von Richthofen was president of the Berlin Geographical Society and he founded the Oceanographical Institute of Berlin. He is still regarded as a dominant influence in modern German geography.

Paul Vidal de la Blache (1854–1922) was a distinguished scholar and the master of French geographers. Acknowledging his debt to Ritter who had strongly influenced him, he refashioned geography by his teaching and writing. Trained in history, geography, and the classics, and widely traveled, Vidal de la Blache united the study of sociology with geography, infusing the French school with a humane spirit which it has since retained.

In 1902 he prepared for Lavisses's *Histoire de la France* a masterly paper, *Tableau Géographique*,^[23] which has become a classic in geographical literature and played a major role in developing the concept of regions. In it he analyzed and interpreted the "geographical personality" of France. Vidal de la Blache never completed a systematic work on human geography, but he expressed his views in many articles published in *Annales de Géographie*, which he founded. In his work he stressed three topics—physical geography, biogeography, and human geography. These were welded together to make up the territorial units within which a distinctive way of life flourished. He also believed that in seeking to understand a human region, history cannot be neglected; and so history and geography were joined together on a sounder basis than they were in the days of Carl Ritter. His most original and important work was *France de l'Est* (1917),^[24] devoted to the study of the foundation of landscapes and rural societies in Alsace and Lorraine.

Jean Brunhes (1869–1930) was a pupil of Vidal de la Blache. His *La Géographie Humaine* (1910)^[25] limited human geography to human phenomena that modify nature, and at the same time are modified or controlled by it, e.g., unproductive occupation (houses, settlements, roads); cultivation and stock raising; and destructive economy (mineral exploration, deforestation).

Another pupil, Albert Demangeon (1872–1940), studied the use of archives in establishing the past human geography of a region.^[26] His study of Picardy is a model of regional geography.

Alfred Hettner (1859–1941) contributed to the methodology of geography.^[27] To him geography was the study of the different characteristics of various regions, resulting from their soil types, plant cover, and the results of man's activity. Studying such phenomena on a worldwide scale enabled the geographer to establish a general comparative geography. In 1895 he founded the *Geographische Zeitschrift* as a forum for the general problems of geography.

Before Halford John Mackinder (1861–1947), British geography was largely centered on exploration. Geography did not become a "proper" subject until 1887 when Mackinder, at the age of 26, was appointed to Oxford University, half his salary being paid by the Royal Geographical Society. His great energy, and his gift for stimulating and brilliant generalizations were indelibly impressed on British geography.

In that same year he lectured to the Royal Geographical Society on the scope and methods of geography, defining it as "the science whose main function is to trace the interaction of man in society and as much of his environment as varies locally," and "the science of distribution, the science, that is, which traces the arrangement of things in general on the earth's surface." Mackinder's lectures, particularly those in historical geography, always drew large audiences.^[28] In 1902 he published *Britain and the British*

Seas,^[29] which is now considered as a classic of British geography; it summarizes the fundamental concepts based on his wide reading and thought, followed by a summary of British history in relation to this background.

His paper "The Geographical Pivot of History" brought him unexpected fame. In it he stated that the maritime age had passed and that land powers would be decisive; that the greatest land area was in the Old World, the heart of which lies within continental or arctic drainage; ringing this "heartland" is an inner crescent of marginal states, with an outer crescent of overseas powers (Great Britain, the United States of America, and Japan). If the balance of power should favor the pivot state, it would then expand over the marginal lands of Eurasia, permitting the vast continental resources to be used for building fleets of ships, thus permitting a world empire. Because of this threat the overseas powers would be obliged to maintain bridgeheads, thus forcing the "pivot allies" to develop their land forces and preventing them from maintaining large fleets.

Mackinder developed his "heartland" theme in *Democratic Ideals and Reality* (1919)^[30] in which he maintained that whoever rules eastern Europe commands the Heartland; whoever rules the Heartland commands the World Island; and whoever rules the World Island commands the World. This theory attracted little attention when it first appeared, but was later taken over by German geopoliticians. Mackinder's influence is still strong, and his ideas are still being developed.

William Morris Davis (1850–1934), a pioneer geomorphologist, laid solid foundations for the study of modern physical geography and established geography as a subject in American universities.^[31] His work exerted considerable influence on the subject, and he was the founder of the Association of American Geographers. In his studies of erosion cycles Davis did not forget the relationship of man's activities to various landforms. In this his influence was felt by other geographers. His emphasis on the time factor has since been established in the concept of "dynamic geography."

Davis's pupil Ellsworth Huntington (1876–1947) stressed the influence of climate on the life and activities of man and the relationships of the distribution of culture with the world's main climatic regions concluding, as did Carpenter, that western Europe was climatically the most favored region for human activities. Huntington trained originally as a geologist, but as a result of a trip to Tibet and central Asia changed to climatology. His hypotheses that central Asia would progressively break up as an influence in the historical and human geography of the continent caused much controversy. He wrote *The Pulse of Asia* (1907),^[32] *Civilization and Climate* (1915),^[33] and *The Mainsprings of Civilization* (1945)^[34] which summarized much of his life's work.

Isaiah Bowman (1878–1950) is considered foremost among modern geographers. He began his career as a

physiographer, and later was inspired and influenced by Davis. His first important publication, *Forest Physiography: Physiography of the United States and Principles of Soils in Relation to Forests* (1911),^[35] constituted a sound basis for the study of North America's physical regions. *The New World: Problems in Political Geography* (1921)^[36] is a valuable source of political and human geography as they were affected by the peace settlements made after World War I. Bowman was director of the American Geographical Society from 1915–1935, and was adviser to the American delegation to the Peace Conference at Versailles. He was always quick to seize opportunities to advance the status of geography in academic circles and the world of public affairs.

The foregoing gives only the barest outline of the history of the literature of geography up to the early years of the twentieth century. Those geographers so briefly discussed were the giants, but there were numerous others who also contributed to the science with their field work, their theories, or both. To have given proper credit to all concerned would have necessitated a several volume work.

As an academic discipline geography has continued to grow and mature, to the extent that no one geographer can any longer be competent in all branches of the field, specialization being necessitated by the new scope of the old subject. Always a dynamic field, geography is continuously changing its methods and tools, striving to provide accurate and useful descriptions of our planet.

Since World War II when the position of geography was consolidated, the number of geographers has greatly increased, as have university departments of geography and so, as a natural consequence, has the literature. Modern geographers, like their spiritual forebearers, are great travelers, theorists, and writers. Some do write books, but generally important works appear as articles in geographical journals (which in turn are usually published by geographical societies). The following is a list of thirty geographical serials^[37] considered to be of "particularly broad international value and interest."

Annales de Géographie: Bulletin de la Société de Géographie, Paris, **1**, 1891, 6/yr.

Association of American Geographers. Annals, Washington, DC, **1**, 1911, 4/yr.

Australian Geographer, Geographical Society of New South Wales, Sydney, **1**, 1928, 2/yr.

Australian Geographical Studies, Institute of Australian geographers, Hobart, 1963, 2/yr.

Cahiers d'Outre-mer; Revue de Géographie de Bordeaux, Université, Faculté des Lettres et Sciences Humaines. Institut de Géographie; Institut d'Outre-Mer de Bordeaux; Société de Géographie de Bordeaux, Bordeaux, **1**, 1948, 4/yr.

Canadian Geographer. Géographe Canadien, Canadian Association of Geographers, Toronto, **1**, 1951, 4/yr.

- Economic Geography*, Clark University, Worcester, MA, **1**, 1925, 4/yr.
- Die Erde. Zeitschrift der Gesellschaft für Erdkunde zu Berlin*, Berlin, **1**, 1853, 4/yr.
- Erdkunde: Archiv für wissenschaftliche Geographie*, Bonn, **1**, 1947, 4/yr.
- Geoforum. Journal of Physical, Human, and Regional Geosciences*, Braunschweig, Germany, **1**, 1970, 4/yr.
- Geografiska Annaler. Series A, Physical Geography*, Svenska Sällskapet för Antropologi och Geografi, Stockholm, **47**, 1965, 4/yr.
- Geografiska Annaler. Series B, Human Geography*, Svenska Sällskapet för Antropologi och Geografi, Stockholm, **47**, 1965, 2/yr.

[The preceding two serials succeed *Geografiska annaler*, **1–46**, 1919–1964.]

- Geographia Polonica*, Polish Academy of Sciences, Institute of Geography, Warsaw, **1**, 1964, irregular.
- Geographical Journal*, Royal Geographical Society, London, **1**, 1893, 4/yr.
- Geographical Magazine*, London, **1**, 1935, 12/yr.
- Geographical Review*, American Geographical Society, New York, **1**, 1916, 4/yr.
- Geographische Zeitschrift*, **1–50**, 1895–1944; **51**, 1963, Wiesbaden, 4/yr.
- Geography*, Geographical Association, Sheffield, **1**, 1901, 4/yr.
- Institute of British Geographers. Transactions*, **1**, 1935, London, 3/yr.
- Journal of Tropical Geography*, Departments of Geography, University of Singapore and University of Malaya, Singapore, **1**, 1953, 2/yr.
- Méditerranée; Revue Géographique des Pays Méditerranéens*, Instituts de Géographie des Facultés des Lettres et Sciences Humaines d'Aix-en-Provence-Nice. Gap, **1–10**, 1960–1969; n.s., 1970, 4/yr.
- New Zealand Geographer*, New Zealand Geographical Society, Christchurch, **1**, 1945, 2/yr.
- Noroi; Revue Géographique de l'Ouest et des Pays de l'Atlantique Nord*, Universités de Caen, Nantes, Orléans-Tours, Poitiers, Rennes, Rouen, Brest, et Limoges, Poitiers, **1**, 1954, 4/yr.
- Österreichische Geographische Gesellschaft. Mitteilunge*, Vienna, **1**, 1857, 3/yr.
- Petermanns geographische Mitteilungen*, Geographische Gesellschaft der Deutschen Demokratischen Republik, Gotha, **1**, 1855, 4/yr.
- Revista Geográfica*, Instituto Panamericano de Geografia e História. Comissão de Geografia, Rio de Janeiro, **1**, 1941, 2/yr.
- Revue Géographique de l'Est*, Instituts de géographie des Universités de Besançon, Dijon, Metz, Nancy, Reims, et Strasbourg, Nancy, **1**, 1961, 4/yr.

- Soviet Geography: Review and Translation*, American Geographical Society, New York, **1**, 1960, 10/yr.
- Tijdschrift voor Economische en Sociale Geografie (Netherlands Journal of Economic and Social Geography)*, Koninklijk Nederlands Aardrijks-Kundig Genootschap, Rotterdam, **1**, 1910, 6/yr.
- Zeitschrift für Geomorphologie. Annals of Geomorphology. Annales de Géomorphologie*, Stuttgart, **1–11**, 1925–1940; n.f. **1**, 1957, 4/yr.

CONCLUSION

It is in publications such as these that the modern classics of geographical literature can be expected to be found.

Germany: Libraries, Archives, and Museums

Claudia Lux

Central and Regional Library of Berlin (ZLB), Berlin, Germany

Abstract

This entry discusses the role and status of German libraries, archives, and museums, with a focus on the two decades following the Reunification of Germany. Although the emphasis is on contemporary trends and issues, a short historical overview is provided. Major topics include: library legislation, public, school, and research libraries and programs for professional education as well as archival science and archival institutions (national, state, and local). There is also a discussion of museology and profiles of major museum in range of areas including archaeology, fine arts, national and local history, natural history, and science and technology. Digital projects are also discussed as are numerous cooperative efforts among libraries.

INTRODUCTION

The Federal Republic of Germany is situated in the center of Europe and is bounded on the north by the Baltic Sea and the North Sea. Germany has 16 Federal States (Länder) with the capital Berlin (Fig. 1). In February 2008, the population was over 82 million with a high percentage of inhabitants over 50 years old; migrants make up approximately 9% of the population. The strong economy manifested by a trade surplus is not always mirrored at the community or state level, as the money earned goes to global players. The percentage of unemployed persons in June 2008 remained at 7.5%. Since the Reunification of East and West Germany in 1990, there slight decline in population and the gap between rich and poor has increased.^[1]

Germany is known as a nation of poets and thinkers—from Goethe and Schiller to Heine and Rilke, from Hegel and Kant to Adorno and Heidegger. It is a nation as proud of its cultural heritage as of its technical inventions like Gutenberg's printing press. Before the German Empire in 1871 was founded and even after, many formerly independent regions and small kingdoms had their own cultural activities. They supported musicians from Bach to Beethoven and commissioned works from celebrated artists such as Albrecht Durer and Caspar David Friedrich. Local rulers and noble families built up collections of precious books, hand-painted maps, and beautiful art works and crafts. This pluralistic cultural heritage strongly influenced the decision for political federalism in culture and education when the Federal Republic of Germany (Bundesrepublik Deutschland—BRD) was founded in 1949. A second reason was the still remaining resistance to the centralized censorship in culture and education during the terror regime of the Nazis.

In contrast to the BRD, a centralized structure in culture and education was kept in tact in East Germany

during the years 1945–1990 when the German Democratic Republic (GDR) existed. After World War II, there were two very different political systems in Germany—one being embedded in the Western bloc with the political influence of the Allied Forces, and the other integrated into the Eastern bloc with an even stronger influence by the Soviet Union. Both systems had different impact on the respective cultural institutions. Different standards and methods were introduced. In the Western part, libraries developed step by step and open stacks were introduced, first in public libraries and from the end of the 1960s also in some university libraries. In contrast, all research libraries in the GDR had reading rooms with reference works and a catalog from which one could find the call number and then request the desired work from the collection that was kept in closed stacks. There were not many official contacts between the two parts of Germany during that time and certain libraries, archives, and museums whose collections had been divided during the bombing in the Second World War remained separated after the War because of the political split. Only after the Reunification did it become clear what the real losses were—not only from the First and the Second World War but also through Nazi Tyranny, the book burnings and destruction of many authors' books in the libraries. A cultural generation of poets, musicians, and artists were killed or emigrated and their art and books were destroyed. Shortly after World War II, the Russians took away many cultural works as compensation for their losses during the War. All the cultural activities in both parts of Germany were monitored, either by Allied troops from United States of America, France and Britain or by Russia. During the process of Reunification of West Germany and East Germany in 1990, federalism was revitalized and this became the foundation of new developments in culture and education.

Modern information services began to be established at the end of the 1970s and the beginning of the 1980s in

Fig. 1 Map of Germany.

German libraries. There was increased progress toward the end of the 1990s and into the twenty-first century with the integration of many Internet services and digital libraries' available through the Internet. Archives and museums started to use technology some years later, but made great progress as soon as digitization became more common.

In December 2007, after 4 years of work, a Parliamentary Enquête Commission on Culture in Germany finished its report.^[2] The report gives an excellent overview of the legal framework for culture in Germany. Many specific recommendations for libraries and museums are presented and an important outcome of the work of this Commission is the strong commitment in support of a library law at the Länder level.

LIBRARY AND INFORMATION PROFESSIONALS IN GERMANY—SYSTEMS AND SERVICES

Brief Overview

The German library system with its approximately 11,500 libraries is organized on four levels of service provision to meet the public's information and literature need:^[3]

Level 1: First level information needs should be met by small and middle-sized public libraries, i.e., by public libraries in villages or small towns, branch libraries, or bookmobiles.

Level 2: This level represents an increased need for books and information, to be met by city libraries especially by their central library.

Level 3: The needs for specialized information and literature are to be met cooperatively by some metropolitan libraries, special libraries, and university libraries in the region.

Level 4: This level refers to highly specialized needs that can only be met in cooperation on the part of designated special libraries, university libraries with their special collections, the three central specialized libraries, and last but not least, the libraries with national collections and services.

There is no general public library law at the national level, and at the state level public library legislation has just started to be enacted. In Thuringia, the first law concerning public libraries was passed at the state level in July 2008 and this puts libraries in an important position as educational and cultural institutions.^[4] There are various laws on different governmental levels in regard to their responsibility for libraries. For example legislation regarding responsibilities of the National Library of Germany was renewed in 2007.^[5] At the state level in Germany there is legislation from 2005 with regard to regional libraries (called *Landesbibliothek*).^[6] Interlibrary loan between libraries in different states in Germany also requires an agreement of all states. To facilitate this, the Conference of the Ministers of Culture from all 16 Federal States—which is the highest cultural organ—has to formulate a common agreement, which is then passed by each state legislature individually before it can begin to function.

National Library and Information Services

The National Library of Germany was founded as the *Deutsche Bücherei* in 1912 by German publishers in cooperation with the Kingdom of Saxony and the city of Leipzig. In 1970, the *Deutsche Bücherei Leipzig* was assigned the function of being the central coordination institution for bibliography in the German Democratic Republic. In 1947, when Germany was divided, publishers of the Federal Republic of Germany founded the *Deutsche Bibliothek* in Frankfurt am Main as their bibliographical center. In 1969, it changed its status under public law and became a federal cooperative agency for all the states, with legal deposit and support by the Federal Republic of Germany. One year later in 1970, the Music Archives were created in West Berlin to receive deposits of all musical works and production. The *Deutsche Bücherei Leipzig* and the *Deutsche Bibliothek* with the Music Archives as a department were united in 1990 under a new name: "*Die Deutsche Bibliothek*." In June 2006, a new law changed the name of the institution into *Deutsche*

Nationalbibliothek (=German National Library). The same law reconfirmed support for the national legal deposit at this Library which receives two mandatory deposit copies of each of the more than 100,000 items published in Germany every year. According to the collections policy with regard to German language literature, the German National Library not only receives materials from Austria and the German-speaking part of Switzerland but also collects German-language publications worldwide. Now the law includes online publications to be collected by the library, cataloged, and stored as part of Germany's cultural heritage.^[7] The German National Library compiles various series of the Deutsche Nationalbibliographie (=German National Bibliography), which can also be searched online.^[8] The German National Library collects German imprints only from 1913 onward. Due to the history of numerous German kingdoms, it had never been possible to create a unified collection of all printed materials produced in Germany that would be comparable to other large national libraries in Europe. Therefore, the National Library is collaborating with a group of five libraries with significant collections in order to develop a complete collection of printed literature published in German-speaking countries from the beginning of Gutenberg's press, over 550 years ago. This venture is called *Arbeitsgemeinschaft Sammlung Deutscher Drucke* (=Working Group for the Collection of German Imprints) and has led to the creation of a combined virtual national library in which the participating libraries are responsible for the following periods shown in Table 1.^[9]

A national library, besides collecting the nation's production of published works, often collects the most important scholarly literature from all over the world. Again in Germany this task is shared by several libraries on the national level. The Bayerische Staatsbibliothek (=Bavarian State Library) in Munich holds a multitude of Incunabula, but also has important international collections, as does the Staatsbibliothek zu Berlin—Preussischer Kulturbesitz (=State Library Berlin-Prussian Cultural Heritage). These two libraries are very important sources for humanities studies due to their collections of works in all European languages and special collections in Oriental, Asian, and East European languages. The State Library of Berlin is not a regular state library with legal deposit (the legal depository library for Berlin is the Central and

Regional Library Berlin). However, it is a library with rich collections like those of a national library.

On the national level, Germany has three central subject libraries.^[10] They collect national and international materials in their subject area quite comprehensively and function as national resource

- For science and technology at the Technische Informationsbibliothek (=Technical Information Library) in Hanover.
- For medicine and biology at the Deutsche Zentralbibliothek für Medizin (=German National Library of Medicine) in Cologne and Bonn.
- For economy at the Deutsche Zentralbibliothek für Wirtschaftswissenschaften (=German National Library of Economics) in Kiel and Hamburg.

Together with the two state libraries in Berlin and Munich and a few other institutions these are the key institutions for national licenses, fully financed up to now by the German Research Foundation [=Deutsche Forschungsgemeinschaft (DFG)]. The national licenses can be used by all faculty members and interested private persons in Germany.^[11]

Germany—a country with so many different states in its history—has developed a refined system of financial support for special collections in university and state libraries to fulfill the need for highly specialized literature in research. This service can be provided thanks to the “special subject collections system” or nationwide library service of the Deutsche Forschungsgemeinschaft (=German Research Foundation). The German Research Foundation covers 50% of the cost of foreign literature in libraries participating in this program which are then designated as the special subject libraries for that subject area. Libraries participating in this system have to commit themselves to building up and maintaining this collection from their own budget and also to sending this material to another library via the interlending library system, when required. The special material may be searched by subject or region using WEBIS^[12] software that enables the user to find the library with holdings on special subject area—for example Psychology in Trier, English language, and literature in Göttingen, etc. All these activities at the national level is seen as the level 4 in serving the information and literature need of the country. Six regional union catalogs facilitate access to these collections.^[13] A search covering all these catalogs can be executed by the Karlsruher Virtueller Katalog (KVK) (=Karlsruhe Virtual Catalog),^[14] The KVK also provides the possibility to search many different national library catalogs from Australia to the United States at the same time.

Academic and Research Libraries

Academic and research libraries have a long tradition in Germany. In the Holy Roman Empire (962–1806), the first

Table 1 Sammlung Deutscher Drucke.

1450–1600 Bayerische Staatsbibliothek in Munich
1601–1700 Herzog August Bibliothek in Wolfenbüttel
1701–1800 Staats- und Universitätsbibliothek of Göttingen
1801–1870 Universitätsbibliothek Johann Christian Senckenberg in Frankfurt/Main
1871–1912 Staatsbibliothek zu Berlin—Preussischer Kulturbesitz in Berlin
1913–Deutsche Nationalbibliothek in both Frankfurt/Main and Leipzig

university and university library was founded in Prague in 1348. In what is now Germany, the oldest university library is the library of the oldest university—the Ruprechts Karl University in Heidelberg, founded in 1386. In the following two centuries, many German dukes and kings founded universities for the education of the nobility. In 1388, the University of Cologne was founded and quite a few other university libraries like the ones in Erfurt, Würzburg, Leipzig, Rostock, Greifswald, Freiburg, Trier, and Tübingen were established.

Many university libraries did not develop substantial collections until 1800, some not even until the end of the nineteenth century when the Prussian empire started to build up special collections in the university libraries of Prussia. At that time Prussia covered a great part of east and northern Germany with boundaries stretching to the Rhineland. University libraries developed in the beginning of the twentieth century as did individual departmental libraries. During the Nazi regime, university libraries hid or destroyed works by Communist, Socialist, and Jewish authors, and the role of librarians in this dark period of the German history still has not yet been fully investigated.^[15] In the GDR 1945–1990, university libraries became centralized institutions and were part of a regulated system with each library playing a special role in the access structure to Western literature. In the Federal Republic of Germany in the 1970s, many new university libraries were opened with the new concept of open stacks and often these institutions had only one single centrally organized library. This structure is in contrast to the two-level system still in existence in many universities where there is a main university library and many independent faculty and departmental libraries. After Reunification, libraries of the former East Germany received new buildings and upgraded their collections. Some university libraries have developed remarkable service ideas: the 24-hour library in Konstanz (Konstanz University library was the first university library in Germany with 24-hour-opening starting in 2001^[16]); a cooperative subject list of accessible databases from 195 libraries organized by the university library of Regensburg;^[17] and research on digital resources and repositories in projects of the university library of Goettingen.^[18] Following a discussion of open access journals the Regensburg university library developed the Electronic Journals Library (=Elektronische Zeitschriftenbibliothek EZB)^[19] with a very simple method: green for free access to full text, yellow for free access for users from certain institutions, and red no full text access available. Libraries of universities of applied science are oriented toward providing study materials and they have a high rate of duplication in their collections to serve the needs of their students.

At the same time, the European Union has started a reform of European Higher Education which was articulated in the Bologna Declaration of June 1999. The aim of this reform is to make academic degree standards and

quality assurance standards more comparable and compatible throughout Europe.^[20] Since the Bologna Process started, academic institutions in Germany are changing from a self-determined study system to a streamlined Bachelor's and Master's degree program with specified requirements for the students. Bachelor students often need the same books as before, but they frequently use library space for learning and they need information literacy training. To meet those needs, academic libraries have changed to provide far more space with wireless Lan connections, and librarians have been successful in integrating information literacy into the curriculum at some universities.

Public Libraries

German public libraries have gone through various dramatic changes during the 160 years of their existence. In the beginning, city libraries had to collect important publications needed by the administration and they were usually viewed as being open to the public even though only the upper class could have access to them. The first “true” public library was opened on October 24, 1828, in Grossenhain, Saxony, on the initiative of Karl Benjamin Preusker (1786–1871) and since 1995, October 24 is now designated as “Library Day” in Germany. The creation of this library came at the beginning of a political awakening of the German nation which cumulated in the March Revolution of 1848. Many public libraries were founded in the middle and the end of the nineteenth century, supported by private “Bildung” educational initiatives (the word Bildung means more than education, it includes the whole person). These initiatives included the “private reading room movement.” At the same time there were official community activities like the opening of public reading rooms and public libraries, which were sometimes combined with the former city library.

At the end of the nineteenth century, more information about American public libraries reached Germany through the librarian Constantin Nörrenberg who reported on what he observed in his travels. In 1893 Constantin Nörrenberg took part in a library conference in Chicago. His report in ‘Centralblatt für das Bibliothekswesen’ suggested reforms in German libraries. These new ideas influenced the profession and stimulated the movement for creating Bücherhallen (public reading rooms) and public libraries. Many German public libraries were founded during the first years of the twentieth century and another wave of public libraries were founded after the First World War. From 1912 onward an intense dispute arose between Paul Ladewig (1858–1940) from Essen,^[21] who supported a free and tolerant approach of library service and Walter Hofmann (1879–1952) from Leipzig who preferred a strong socio-pedagogical approach.^[22] This dispute still has influence on public libraries in Germany today. Instead of combining the service for the general public

with older and traditional works in the collection, German librarians in their tendency to be very exact, divided library collections and services clearly into research or scientific materials on one side and easy reading material for the entertainment of the public on the other side. After 1945, many new public libraries were founded in the GDR—not only in cities and villages but also in factories. A system of large public libraries called Wissenschaftliche Allgemeinbibliothek (General Research Library), was established to serve the scientific needs of the public. East Germany became known as “Leseland,” a country of reading.

In Germany today small and medium-sized libraries have a good mixture of different books and media to offer at the basic level. In serving people at this level, the library provides a central access point for information and markets its services to everybody. Public libraries at this level are financed by local communities. The libraries’ tasks at levels 1 and 2 include:

- Meeting the citizen’s information needs, by facilitating access to the complex world of books and nonbook resources, including the Internet.
- Supporting the use of new technologies.
- Promoting reading and cultural work within their community.
- Inspiring people to spend their leisure time creatively,
- Motivating learning.
- Helping to integrate different user groups, such as people from different cultural and linguistic backgrounds.

According to the Bibliotheken 1993 libraries at level 2 have to meet the following standards:

- Two books or nonbook items per resident.
- A stock of current periodicals.
- 20% of the collection should be nonbook materials (CD, video, DVD etc.).
- Minimum opening hours of at least 35 hr a week.
- Participation in union cataloging and interlibrary lending systems.
- 5% of the collection should be current reference books that provide extensive information and information about products and prices, as well as about tested technical products.

Libraries at levels 1 and 2 should offer access to selected databases.^[23] The traditional organizational system of the public library is still in existence: there is a central library either with district and branch libraries or just branch libraries. Some public libraries have special music libraries providing musical scores, books on music, and CDs. A special home delivery system for handicapped people delivers books and nonbooks materials; often this service is supported by volunteers. The mobile library stops at

schools and at places outside the city center where there are no branch libraries. One mobile library can serve approximately 25,000 inhabitants.

During recent years, many new public libraries have been built in Germany. Some of these have very interesting architecture; examples include Münster and Ulm which have fascinated architects and librarians alike, and have sparked the development of new concepts for library architecture in Germany. One of the most famous public libraries is the Würzburg library which has won different prizes like the “Library of the Year” prize in 2003 and which was often at the top of the German library benchmarking public libraries of this size. German public libraries have developed interesting concepts for youth libraries all over the country, with good examples in Düsseldorf and Hamburg. The largest public library system in Germany is found in Munich with the traditional central library and many different branches. Munich was the first metropolitan library to use Radio Frequency Identification in bar codes.

The establishment of five or six Combi(Combination)-libraries, where research library and public library are integrated into one organization, illustrates a trend which is not only found in Germany but also in Europe and elsewhere. The most developed integration can be seen in the Central-and Regional-Library in Berlin, where the general books for the public and scientific information and scholarly works are all shelved together. The Zentral-und Landesbibliothek Berlin functions as a public library and as a state library with legal deposit for the city and state of Berlin. The combined Berlin library offers 3.2 million books and nonprint media in an integrated research and public library collection which provides users with a wide range of materials.

Other Libraries for the General Reader

“Factory” libraries are public libraries for the employees of the factory and their families. West Germany was a country with numerous factory libraries up to the 1970s and East Germany had many factory libraries until the change in the industry after Reunification. During the last decade, factory libraries decreased from several 100 to fewer than 50 during the 1990s and the German Association of Factory Libraries dissolved in 2004. In hospitals, libraries for the patients that provide a kind of public library service are still prevalent, but often they are administratively combined with the highly specialized library for the medical staff. Libraries in prisons received more attention when the prison library in Münster won the National Library Price in 2007.

Quite a number of public libraries are financed by the Christian churches with philosophy of practice based on their own cultural traditions. They have fewer opening hours and are run by volunteers.

School Libraries

In Germany only 5% of all public schools have any kind of school library. Some school libraries have a good collection of books and media, enough space, and high speed internet connections. Others have only a small collection of donated books, collected by parents and supported by volunteers. The reason for a lack of school libraries in Germany has its roots in the civil servant hierarchy in which librarians and teachers often have a different status and hence, schools do not usually have the means for employing a librarian for the school.

Special Libraries

Special libraries are often part of their institutions and are focused on internal services. Their collection policy often covers digital research data and grey literature in all kinds of formats. Librarians in these special libraries are often expected to synthesize detailed content information to suit their users' needs and in most cases, these special libraries are not open to the public, although some may allow use of the reading room. Nevertheless, special libraries play an important role in Germany's library services; innovative information services often develop from these libraries' activities in response to their highly specialized users' needs. There are special libraries of research institutes, such as Max-Planck Institutes or Fraunhofer Institutes, which serve the basic research programs in these institutes. These libraries are of high quality and very well financed. Many special libraries in Germany are one-person-libraries and these solo librarians have created a small, informal network for mutual support, and exchange of ideas. Germany has nearly 1000 special libraries, including those located in ministries and in administration, law libraries and medical libraries, and libraries of museums and art galleries.

Digital Library Collections and Services

Digitization is a very important activity of German libraries. From the small special library all the way up to the National Library, digitization is a topic of great interest. There are three important digitization centers, one at the German National Library and a second center at the University Library Göttingen and the third being the Google Library Digitization Project at the State Library Munich. Most of the projects focus on digitization of special collections, incunabula, and older manuscripts. The Google project in Munich is different as it is the first mass digitization project in Germany and is concentrated on the eighteenth- and nineteenth-century collection in Bavaria. There are quite a few other digitization projects which are heavily used, such as the address-books of Berlin from 1799 to 1943 at the Central and Regional Library in Berlin^[24] or the digital Gutenberg Bible^[25] at the

University library of Göttingen. Many of the ongoing digitization projects are cofinanced by the German Science Foundation, which supports library technological development and cooperative research library activities for better science.

LIBRARY AND INFORMATION SCIENCE AS A DISCIPLINE AND A PROFESSION AND LIS EDUCATION

Library and Information Sciences is offered as a discipline in different types of institutions. There is only one academic university—the Humboldt University in Berlin—which offers a doctorate as well as a Bachelor's and Master's degree. Although the Master's degree will soon become the qualification needed by professional librarians an older system of credentialing is still in place. In the past, to become a professional academic librarian, the candidate must have already completed a university diploma or master's degree in some field like German literature, history, or physics, before he or she is admitted to a 2-year course of library and information science to get a second master's degree in this field. This qualifies him or her to work as a subject librarian at the university level and for different higher management positions including the head librarian position at larger public libraries.

Since the Bologna process has altered the European higher education practices, the former course for certified librarian or Diplom-Bibliothekarin at different universities for applied sciences has now changed to a Bachelor's degree in library and information science. This training program qualifies the candidate for cataloging and many other positions in university and research libraries as well as for management positions in small- to medium-sized public libraries and special libraries.

At the lower level, students who have completed the 10th grade (or German middle school) may enroll in a 3 year vocational training program to become a specialized employee in media and information services. This is an integrated qualification for work in libraries, archives, and audiovisual archives. This program is administered like other German vocational training programs, i.e., the training takes place alternating between 3 weeks in a library followed by 3 weeks of courses in a corresponding vocational school for the period of 3 years and requires a series of final examinations. This training program provides German libraries with well-qualified young staff able to carry out various tasks from simple cataloging to lending services and periodicals' maintenance to Web page management and so on. In Germany, it is very common that everybody in a library and information service does front desk work (check-out, reference desk, etc.), or public relations work combined with back office work like cataloging or acquisition.

Continuing education is a very important activity in German libraries. Each year the Bibliothekartag (German librarians' conference) is the most important continuing education meeting for German library and information professionals. There are many other possibilities for continuing education for librarians at the level of the Länder and a virtual marketplace makes it easy to find them all.^[26]

Professional Associations

Cooperation is at the heart of *Bibliothek & Information Deutschland* (BID = Federal Union of German Library & Information Associations), the national federation of library associations, founded in 1989 as an umbrella organization of German library and information associations. This umbrella organization unites four major association:

1. *The Deutscher Bibliotheksverband* (DBV—German Library Association), represents 1700 institutions and includes both academic and public libraries. DBV was created in 1949 and in 1991, after being separated for 27 years, the German Library Association (East) and the German Library Association (West) reunited.
2. *The Berufsverband Information Bibliothek* (BIB—Association of Information and Library Professionals) has 6300 members and is the largest association of library and information professionals. It was founded in 2000 through a merger of four separate associations. Its members include many public librarians and library assistants.
3. *The Verein Deutscher Bibliothekare* (VDB—the Association of German Librarians) the oldest librarian association in Germany, was founded in 1900. Most of the library directors and many professional librarians in Germany are among its members. Its membership includes academic and research librarians with university degrees.
4. *The Deutsche Gesellschaft für Information* (DGI—German Society of Information) founded in 1948, represents documentalists and information specialists.

The German Library Association (DVB) has developed and has taken the leadership of a Competence Network of Services like the library statistics and the library portal for Germany.^[27] This library portal is the best information source about libraries in Germany.

ARCHIVES AND ARCHIVAL SCIENCE IN GERMANY

Overview

Germany's archival law was issued in 1988 in the Federal Republic of Germany with amendments added in 2005^[28] that apply to the freedom of information legislation

concerning the accessibility of archives and official records by everybody. Following World War I the first national archival law of 1919 created a central archive for all historical records. Today, materials in all formats (printed materials, maps, data and images, and films and sound recordings) produced by government agencies at different levels must be collected by the Bundesarchiv (=Federal Archive). In a federal state like Germany there is a national archival law and there are archival laws in the different federal states (Länder) to regulate archiving of government records at all levels.^[29] The national law of January 1988 establishes the basic rules for the legal deposit of official records for all administration and government agencies at the national level, and regulates the organization and the accessibility of these records. An important part of the archival law is the question of delayed access. In general, archival records are accessible to the public after 30 years; however, records containing personal information or having special security concerns (medical records, tax data, etc.), are not accessible for 60 years. Other personal data can be accessed 10 years after the death of the person, although there are exceptions to this concerning the official records of the German Democratic Republic. They are freely accessible by law.

The history of Germany with its many small kingdoms is reflected in the development of archives at the state and regional levels. In managing historical records of a territory, archivists must cope with many situations where boundaries recognized in the past often differ from the current political borders of the territory. An excellent overview on archives in Germany has been produced by the Archivschule Marburg which lists State archives at the level of the Länder, community archives, and all other kinds of archives in a full list.^[30]

National Archives and Services

The Bundesarchiv (=Federal Archive) in Koblenz is the central Federal archives in Germany and is under the State Minister of Culture and Media of the Federal Republic of Germany. Some of its records go back to 1411, but the regular collection of records started in 1867, just 4 years before the Foundation of the German Empire in 1871. The Federal Archive is the successor of the Archives of the German Empire that was founded in 1919. The Federal Archive is responsible for collecting the records of all federal constitutional bodies, government, and courts, except the parliament. After Reunification in 1990, the development of eight branches of the Bundesarchiv shows the integration of the two parts of Germany very well. In Koblenz, the records of the Federal Republic of Germany are maintained, in Berlin the records of the German Reich and its successors since 1871, and all other records from 1495 to 1871 except the time from 1807 to 1814 when Napoleon occupied Germany (this archive is in Paris). The Berlin Branch of the national archive keeps the record of

East Germany and of a foundation which was created to protect the records and documents of parties and mass organizations of the GDR (Stiftung Archiv der Parteien und Massenorganisationen der DDR im Bundesarchiv).

As part of the Federal Archives the Berlin Film-Archive is the biggest film archive of the world. The Bayreuth Branch keeps records concerning lost property of Germans in former German territories and former GDR as the records on the search services of the Red Cross, which played an important role after the Second World War 1945.

The German Military Archive is kept in the Freiburg Branch of the Federal Archive and in Ludwigsburg the records of Nazi Crimes can be found. Many records were destroyed during the Second World War 1939–1945, as was a part of the former Military Archive of the Army.

There are four other important Archives at the national level: First:

- *The Parlamentsarchiv des Deutschen Bundestags* (=Archive of the German Bundestag) with all parliamentary records since the Federal Republic of Germany was founded in 1949, and some records from 1945 to 1949 of the military government of the Allies.
- *Die Beauftragte für die Unterlagen des Staatssicherheitsdienstes der ehemaligen Deutschen Demokratischen Republik* (=The Office of the Federal Commissioner for State Security Services of the former German Democratic Republic) preserves the records of the former Ministry for State Security in its archives and makes these available to private individuals, institutions, and the public in accordance with strict legal regulations. These legal regulations differ from the archive law, as there is a special law for this archive which makes it possible to have access to files on persons.^[31] In the archive of the central office in Berlin and in the 14 archives of the outposts of the Federal Commissioner, one can find the records of the former intelligence service of the GDR which developed during the four decades of the existence of the Ministry for State Security. This archive is very active in public relations and often presents results of the research to the press when politicians or other public persons are confronted with their past—as victims or as employees of the Ministry of State Security in the German Democratic Republic.
- Another very important Archive at the national government level is *the Politische Archiv des Auswärtigen Amtes* (=The Political Archives of the Foreign Ministry) with all bilateral and international contracts from 1876 up to the present.
- Last but not least the *Geheime Staatsarchiv Preußischer Kulturbesitz* (=Secret Central Archives of Prussian Cultural Heritage)—a name applied in 1803—can be traced back to 1282 with a location in Brandenburg and it became an autonomous body

in 1598. This archive is no longer secret and provides access to records from 1188 to 1933 relating to Prussia including the history of the king's family and the archive of the Foundation Prussian Cultural heritage since 1957.

German State Archives (Landesarchives)

In the 16 federal states of Germany today, the central state archives or Landesarchive together with some archives of special territories contain important collections of official archives. Due to the historical existence of many duchies and kingdoms, “state” archives have been developed by small territorial units, not identical with the political boundaries of the German states (Länder) as they presently exist. There is still two-tiered structure of archival responsibilities in some of the German federal states, especially those with double names. Since 2003, there have been some organizational changes. First in the state of Saxony-Anhalt, later in North Rhine-Westphalia, Lower Saxony, and Saxony and Baden-Wuerttemberg, the archives of smaller territories have been integrated in one Hauptstaatsarchiv (=central state archive) or Landesarchiv of the respective federal state. This practice has created a single streamlined organization in each these states, as well as a standardized appraisal policy, and it will prepare for the next step toward a digital future.^[32] At the level of the Länder, the archives have the task to collect material of the state governments including the ministries, administrative units, and courts at this level. Just as the National Parliament has its own Bundestagsarchiv, the state parliaments also have their own parliamentary archives. Many archives on the level of the Länder also collect materials from parties and civil organizations. The archives in the new Länder of former East-Germany also have files from the former state-owned companies and factories. Parliaments of the Länder have their independent archives or deposit their archival materials at the state archive. The archives in North Rhine-Westphalia have collected a Linklist as a guide to using materials in all kind of archives in this region.^[33]

Local Archives in Germany

Germany has a very strong community life with more than 12,000 cities, districts, and villages. At the local level, Germany has city archives and county archives. In addition to collecting the records of the local government and the local courts, these archives are active in obtaining materials about civil organizations and famous persons. Besides the official records at this level, many kinds of local organizations have created historical records. There is a saying that wherever there are three Germans, they will found an organization. In many cases, records of local groups may be collected in a community archive. Some of

the local archives have special materials like calendar collections, leaflets and posters, and theater programs and postcards. To support communities with archival services and to give advice on archival problems, in some parts of Germany, such as Brandenburg and Westfalen, service institutions for archives have been established to support the local level. As we have seen, the history of Germany as a country is more complicated than in centralized states, and this is mirrored at the local level, where the situation is even more complicated. Preparations for research in a local archive must be accompanied by a good knowledge of the region's history, what state it belonged to in which time period. Only with this detailed information is it easy to determine the correct archive that was responsible at that time for collecting the files. The principle that the archive must be organized according to the principles used by the government then in power is a very important principle for Germany's changing landscape of small territories over centuries.^[34]

School Archives and University Archives

Archives of famous schools, especially of some of the early secondary schools (Gymnasien) in Germany, have been maintained very well. One example is the school archive of the Berlinische Gymnasium zum Grauen Klosters held in the Central and Regional Library in Berlin. This is a school which many famous people attended and where you still can find the grades of Bismarck, the first chancellor of the German Empire. All records of students and teachers have been kept since 1574.

All universities in Germany have their own university archives, which is often part of the university library and collect student data and documents of the university administration and manuscripts of famous professors. Some of the old university archives like Heidelberg have a long tradition but may have lost documents during times of war in the seventeenth, nineteenth, or twentieth century.

Film Archives and Other Audiovisual Archives

The most important film archive has already been mentioned as a part of the national archive. The most important audiovisual archives are those from the radio and television stations. The ARD Radio stations and other public radio and television stations have maintained public archives from the beginning of radio and television in Germany. The Deutsches Rundfunkarchiv in Potsdam is supported by all public radio and television stations in Germany and has to be especially mentioned because its collection includes the first public radio announcement from October 1923. Current activities include the SWR 2 archive radio with presentation of interesting features from the archive.^[35] The German Music Archives collect all audiovisual media on music and is part of the German National Library. Besides the Bundesarchiv one of the

biggest image archive with 12 million images is the Bildarchiv Preussian Cultural Heritage. In Dresden, the Deutsche Fotothek, a famous archive with more than 800,000 photos, is a part of the university library.

Literary Archives

In the tradition of the classical literature, Germany has quite a few archives of literary figures—the extensive Goethe and Schiller archives in Weimar are only one model. The Literature Archive in Marbach is the main institution that holds manuscripts and typescripts of many German authors and poets. There are some other literature archives with a special focus on regional authors, more or less famous, like the Theodor Fontane Archive in Frankfurt/Oder.

Corporate Archives

Corporate archives are known for being less well organized and are often integrated into the archives of the Länder, state libraries, or university libraries. For example, the 200-year-old library and the corporate archives of the family of Thurn und Taxis, which started the first private postal system in Germany, was given to the university library in Regensburg as a deposit. Other large companies still have their own corporate archive like Krupp in Essen and are able to answer requests from interested persons. The family archives for family-owned concerns are often integrated with the documents of the firm. When companies are dissolved, regional economic archives collect some of those records. A good example is the Bergbauarchiv in Bochum for the coal mining industry of the Ruhr District.

Religious Archives

In Germany, the main type of religious archives are from the Catholic and the Protestant churches with their diocesan or state-level church archives. Protestant archives at the local church level are the most important local sources for genealogy research. Social activities for the poor and for orphans are also well documented in these archives.

Private Archives

Quite a few historical societies have their own archives as do important families. Many family archives of nobility or important men and women are found in Germany, and, if they are not collected by the state archive, they remain in the hands of the families. The nobility has played an important role in Germany in agriculture, economy, military, civil services, and as public persons. Therefore, the archives of nobility like the Deutsches Adelsarchiv (=German Nobility Archive) may have important historical records. In Germany, some active special interest

groups have created important private archives as a grassroots initiative: these include the women's archive, the migration archives, and others called Archive von unten (=Archive from the grassroots). One of these very special private initiatives that needs to be mentioned here is the Archiv der Jugendkulturen (=Archive of Youth Culture) in Berlin, a private institution which resembles both a library and an archive. This archive collects Fanzine, the magazines and flyers produced by fans, and they also collect all kinds of record about the fan culture. It relies on voluntary contributions. Nowadays, the fan culture is moving to the Net and the Fanzines are produced electronically. So, as in all other archives, this archive faces new challenges. The Archiv der Jugendkulturen produces an electronic list of these records, the Fanzine-Index.^[36]

Digital Archival Collections and Digital Finding Aids

Digitization as a form to give access to archival materials is being discussed. The Bundesarchiv in Koblenz and the Berlin branch were very active in digitizing finding aids of their archives. Finding aids are presented at the homepage of the institution. All other archives are increasingly placing their finding lists on the Internet, like the Berlin Landesarchiv. In contrast to the libraries, the discussion on digitizing the material itself is not so intensive. The amount of time spent on doing digitization is judged in relation to the importance of the records. There are many projects on digitization supported by the German Science Foundation, focusing on the conversion of the finding aids. One of the first activities to digitize archival documents was the digitization of the pre-eighteenth century records of the Archive of Duderstadt. This was a project in connection with the Max Planck Institute of History in Göttingen. It was also a pilot program for long-term conservation.

In contrast to Germany's libraries, the archives do not enjoy the same kind of cooperation. During recent years this has changed and more cooperation and discussion has started. The digitization activities are growing, but prior to this there were many successful efforts to save archival records on microfilm. New cooperation has begun with the cooperative cataloging of manuscripts in Kalliope, a central catalog of manuscripts in Germany, run by the State Library Berlin Prussian Heritage.^[37] There is information about 1.3 million manuscripts and for over 400,000 individuals. Approximately 300 libraries and archives are cataloging their manuscripts in this database, which is a partner of the BAM-Portal, a Web server for libraries, archives, and museums.

ARCHIVAL SCIENCE AND EDUCATION

Archival science becoming more important in Germany. Educational programs for archivists and records managers

are offered at various levels and there are ongoing discussions concerning examinations, certification, university level programs, and continuing education.

Besides, the Fachangestellte für Medien und Informationsdienste with their integrated training program for work in libraries, information and media centers or archives, one category of the archivists employed in Germany are still trained according to the rules for civil servants. This means, to become an archivist, with a credential comparable to a bachelor's level degree, the Landesarchiv, or state archive select candidates with high school degree (Abitur). They go through a 3 year program including a 4 month training module at a school of administration and on-the-job training periods in the archive which has selected the student. At the end, the student passes a professional certification examination for civil servants in archival institutions. Then he or she is able to look for the middle management level position in German state archives.

The higher level of civil servants are selected by the State Archives. As a prerequisite, they must have finished a full course of university study, a master's degree, preferably in history, and they are encouraged to have a doctorate. Following an 8-month training period in the archive, the candidate for this level has 12-month program of study at the School for Archivists in Marburg, and a 1-month internship at the Bundesarchiv. Certain universities of applied science in Germany have changed the former Diplome-programs for archivists to bachelor and master's degree programs of study. The 3- to 4-year courses include one semester of work experience at an archive. At the University of Applied Science in Potsdam, preparations for the start of a nonconsecutive master course for working archivists have begun, following the distance learning model for librarians at the Humboldt University in Berlin. The consecutive master's course will start in 2010. The most famous school for archivists is the Archivschule Marburg, a university of applied science solely for archival studies. Its library is the special library for archival science in Germany.

Professional Associations

The main professional association of archivists is the *Verband Deutscher Archivare und Archivarinnen* (VdA) (=Association of Archivists) founded in 1946. With 2200 members it is the largest association of archivists in Europe. Archival appraisal is discussed in the position paper of a working group "Archival Appraisal" within the Association of German Archivists.^[38] The association publishes papers on basic principles, standard procedures and as special problems like handling large quantities of similar case files, statistical records, electronic, and audiovisual records with checklists. These publications help to build a common level of appraisal in state and local archives in Germany. Since November 2008, the

association has a new working group on archival documents of the twentieth and twenty-first century.^[39]

Electronic Records

There is an ongoing discussion about using electronic records, about the complexity of permanent data retention and other issues. In many German archives, the focus is now changing to long-term preservation of electronic records—a very difficult task as government agencies and administrations use different technologies for their archival systems.

Preservation of Documents

Preservation and conservation is one of the main challenges in German Archives. Since 1961, a selection of archival documents of national and state archives are preserved additionally by preservation microfilming, supported by the Bundesamt für Bevölkerungsschutz und Katastrophenhilfe (=Federal Office of Civil Protection and Disaster Assistance).^[40] Methods of restoration and conservation of the materials including removal of mould and deacidification are regularly discussed as paper made between 1840 and 1990 contains acid and German companies have devised different methods to extract the acid and stabilize the paper.

Other Issues

Archival pedagogic or user education is new to the archival field, as is public relations work for the archives in Germany. More and more activities are initiated by key archives for the public, including not only exhibitions but also discussions for students of middle school who are doing learning projects on history.

MUSEUMS AND MUSEOLOGY

National Museums

There are more than 6000 museums in Germany. Most of them are organized at the community level. At the level of the federal states (Länder), there are Landesmusseen (State museums), as well as other special and more important collections. Due to the federal structure, there is not one National Museum in Germany. Instead, there are several museums at the national level supported by the Federal Minister of Culture together with the Länder. Today, some of these museums are organized as a public foundation or a limited company, with representatives of the national government on the board of trustees, often together with those from the Länder.

The most important museum complex of this kind is the *Stiftung Preussischer Kulturbesitz* (=The Prussian

Cultural Heritage Foundation) and its museums, libraries, and archives. The Foundation was created in 1957, and two-thirds of its budget is financed by the Federal Government of Germany and by the 16 Länder.^[41] It is one of the largest museum complexes worldwide and the most extensive in Germany with 25 individual institutions altogether. The Museum collection, called the *Staatliche Museen zu Berlin—Preussischer Kulturbesitz*, (=Berlin State Museums—Prussian Cultural Heritage) originated with collections of the treasures of the Prussian kings and emperors, and on the travels of important German archeologists. Since Re-unification of Germany in 1990, the collections and museums from the East and the West are united again. Most famous of these is the *Museumsinsel* (=Museum Island) in Berlin, a UNESCO World Heritage Site, with the Pergamon-Museum as its public magnet. This is surrounded by museums with extensive archeological artifacts and nineteenth-century collections. At the *Kulturforum Site* (=Cultural Forum) in the former West part of Berlin is another major complex of art museums with collections of paintings from more than five centuries and galleries with twentieth-century art. The *Dahlem Museums*, another part of the Prussian Cultural Heritage, combines museum collections of ethnology and Asian art. Collections of contemporary art, design, and photography; these collections are located at the Museum Hamburger Bahnhof, at Museum Berggruen and the New National Gallery and at other facilities of this Foundation which includes the *Institut für Museumsforschung* (=Institute of Museum Research) which produces documentation and statistics, as well as research on German museums.

The *Deutsche Historische Museum* (=The Germany Historical Museum), supported by the Federal Minister of Culture, was officially founded in 1987 after a long discussion about the need and relevance of a national museum of history. Opponents saw this as a growing tendency toward nationalism which was at the base of the Nazi ideology—still a sensitive topic in German society. The museum now offers German history from its beginnings, but places this history within the European context. After Re-unification of Germany, the museum moved back to the center of Berlin, and took over the collection of the former Historical Museum of German Democratic Republic.

The *Stiftung Haus der Geschichte der Bundesrepublik Deutschland* (=Foundation House of the History of the Federal Republic of Germany) in Bonn and Leipzig, documents the history and the democratic development of the Federal Republic of Germany since 1945. As the eastern branch of the Foundation, the Leipzig Forum of Contemporary History was opened on October 9, 1999, in recognition of Leipzig as the center of the peaceful revolution in East Germany 1989 which led to Re-unification of Germany. This History Museum collects items of from all media to art, graphic art and political caricatures, designs, textiles and objects of daily life, and currencies.

There is one contemporary art collection at the national level called *Bundeskunstsammlung*. Since 1970, the German Federal Republic collects German art from 1949 onwards. The whole collection is not located in one museum but is placed in embassies, ministries, and public spaces. Today, this collection includes 1200 pieces of art.^[42]

Although culture is the responsibility of the Länder, there is a special law for a “blue list” of those cultural institutions from Western Germany which are cofinanced by the Federal Government. Accordingly, 20 important cultural institutions of Eastern Germany are listed in a so-called “bluebook” of the Federal Government. Some of the following museums of the Länder belong to one of the lists and receive national support as cultural beacons of national importance.

The Castles and Gardens of the Prussian Kings are combined in the *Stiftung Preußische Schlösser und Gärten Berlin-Brandenburg* (=the Foundation of Prussian Castles and Gardens in Berlin and Brandenburg). It was founded in 1994 as a combination of two former institutions in West and East. The foundation maintains and documents the heritage of the castles and gardens including their collections of royal art and interior furnishings.

The *Klassik Stiftung Weimar* (=Foundation of the Weimar Classics) is a large museum complex comprising 11 sites: a library, the archives, and museums of Goethe and Schiller, palaces and historical houses as well as the parks in and around Weimar. The Weimar Classic forms the ensemble Classical Weimar, honoring this famous period in German culture.

Other institutions from the blue list include

- Kunsthalle Bremen (=Art Gallery Bremen).
- Bauhaus-Archiv Museum für Gestaltung (=Bauhaus-Archiv Museum of design) Berlin.
- Schiller Nationalmuseum (=Schiller National Museum) Marbach.
- Franckesche Stiftungen Halle (=Francke Foundations).
- Leibniz Science Society museums.
- The Römisch-Germanisches Zentralmuseum (=Roman-Germanic Central Museum) Mainz.
- Germanisches Nationalmuseum (=Germanic National Museum) Nürnberg.
- Deutsches Museum München (=German Museum Munich).
- Deutsches Bergbaumuseum (=German Mining Museum).
- Bochum, Deutsches Schifffahrtsmuseum (=German Maritime Museum) Bremerhaven.

Major Art Museums and Galleries

Altogether there are about 500 art museums in Germany. Germany's major art museums and galleries are in Berlin, but Munich, Dresden, Kassel, Hamburg, Cologne,

Düsseldorf, and Stuttgart all have significant art museums and galleries. Especially famous are Munich's *Alte Pinakothek* with European masterpieces of the fourteenth to the eighteenth century (one room just for Rubens) and the *Neue Pinakothek* which covers nineteenth-century art. Munich also has the *Pinakothek der Moderne* which collects graphic art from the fifteenth century to the twenty-first century; it also includes one the first design collections that originated in 1907.^[43] The *Staatliche Kunstsammlungen Dresden - The Old Masters Picture Gallery in Dresden*—displays Italian renaissance, Dutch and Flemish masterpieces, Spanish and French paintings of the seventeenth century and older German art as that by Dürer, Cranach, and Holbein. As one of the few museums from Germany represented in the virtual reality of the “Second Life,” there are rooms from this Museum reproduced true to scale with all 750 masterpieces.^[44] The New Masters Picture Gallery is well-known for modern art. The Staatsgalerie (=State Gallery) Stuttgart has art from the Middle Ages up to the modern period, although the Stuttgart Kunstmuseum (=Stuttgart art museum) concentrates on modern art. In Kassel princely state supported museums have very rich collections. The Hamburger Kunsthalle (Hamburg Art Gallery) supported by the Hamburger Kunstverein (Hamburg Art Society) is known for its art from the Northern Germany, from Holland, France, and Italy, with many masterpieces from the fourteenth century. Since 1995, it also has a contemporary section. The development of German artists belonging to the “Brücke” (Ludwig Kirchner, Emil Nolde, and others) is very well represented with 400 art works in the Brücke Museum in Berlin Grunewald. The Bauhaus, a design and architecture school from 1919 to 1933, is represented in the Bauhaus-Archiv Museum Berlin, and in museums in Dessau and Weimar, where the Bauhaus was founded. The art museum of the Land Berlin, the Berlinische Gallery, has a fine collection from 1870 until the present with special themes Fluxus and Dada. The Kunstsammlung von Nordrhein-Westfalen K20 K21 (=the Art Collection K 20 K21 of the Land North Rhine-Westphalia)^[45] is a fabulous collection of the art of the twentieth century focused on Western European and American art (Picasso, Beuys, and Klee). Nearby, the Museum Ludwig of the city of Cologne collects twentieth century and contemporary art, too. This is one of the few museums with Russian avant-garde art of the 1920s and 1930s and is known as the third largest collection of Picasso's works in the world. Frankfurt City's Museumsufer—11 museums at the bank of the river Main—can be seen as a museum complex, representing all kinds of special art collections.

Science and Natural History Museums

Natural history museums in Germany often developed from university collections of minerals, fossils, plants, and insects. At a global level, Germany's various

collections of millions of specimens are of great importance for biodiversity research. There is no one central national museum for natural history but instead, the specimens are divided among 12 major museums and more than 100 smaller ones. Germany's natural history museums comprise seven direct nodes of the *Global Biodiversity Information Facility*. They are responsible for collecting data representing seven major taxonomic groups:

- Insects at the Staatlichen Museum für Naturkunde Stuttgart (=State Museum of Natural Science in Stuttgart).
- terrestrial invertebrates at the Zoologische Staatssammlung München (=Zoological State Collections Munich).
- marine invertebrates at the Forschungsinstitut und Naturmuseum Senckenberg (=Research Institute and Museum of Nature Senckenberg) in Frankfurt.
- animals with vertebrae at the Zoologischen Forschungsinstitut und Museum Alexander Koenig (=Zoological research institute and museum Alexander König) in Bonn.
- botanical specimens at the Botanischer Garten und Botanisches Museum Berlin (=Botanic Garden and Botanic Museum Berlin).
- mycology at the Botanische Staatssammlung München (=Botanic State collection Munich).
- prokaryotes at the Deutsche Sammlung von Mikroorganismen und Zellkulturen Braunschweig (=German collection of prokaryotes and viruses).

In Germany, technical history museums have seen rapid development during recent decades. Due to a total economical change in certain regions in Western Germany and after the Re-unification in the East of Germany, large coal mines, and old steel production sites, as well as abandoned industry sites of different kinds, have been preserved, making Germany very rich in technical history sites. There are large museums of the former mining and steel industry and groups of volunteers run the museums in their leisure time, sometimes supported by the local governments. Other technical museums have a longer tradition, such as those displaying handicrafts and other items that represent the rich diversity of local traditions in Germany's small communities.

The *Deutsches Museum* (=German Museum) in Munich founded in 1903, has one of the richest technical collections of the world. Besides the traditional display of mechanical and technical inventions, the museum has created a transportation museum to explain the development of bicycles, cars, and trains, and in 1992 opened a special airplane museum with an old airport and maintenance hangar outside of Munich.

Established only during the 1970s, the *Stiftung Deutsches Technik Museum in Berlin* (= Foundation of

German Museum of Technology in Berlin) presents impressive exhibitions of technical masterworks ranging from locomotives to small scale technology. Many exhibits with a strong experiential character have been developed in order to involve visitors in all kinds of activities using new interactive concepts. The Museum has opened a new section in 2006—recognizable from afar by an example of the “Raisin bombers” aircraft during the Berlin Air Lift on its roof. The attached Sugar museum 6 km north shows 500 objects on the history of sugar and is typical of traditional museum culture in Germany.^[46] It was founded in 1904 as a part of the sugar industry, before it came under the support of the city and state of Berlin. It is typical for the development of small industry museums in Germany to go from private institutions to ones that are supported by state or local authorities.

On the level of the *Länder*, important museums of crafts and technology are located in Mannheim, Hagen, Hamburg, and many other cities. From the German Radio Museum in Potsdam to the clock museum in Furtwangen or the famous toy museum in Nuremberg, many special museums possess rich collections of crafts and technological inventions. Since Germany is so famous for its organs, clavichords, and pianofortes as well as other instruments like violins, the museums of music must be mentioned. The collection of the *Musikinstrumentenmuseum* (*Museum of Musical Instruments*) in Berlin with more than 3000 instruments is one of the biggest in Germany.

All technical museums are a wonderful world for children and many of them have special tours for children or offer their location for birthday parties in the museum. However, there are only a few institutions specifically designated as children's museums in Germany, and most of these are based on private initiatives like the Exploratorium in Potsdam or the Machmit Museum (Hands-on Museum) in Berlin, where even a few objects like a special “path to feel” can be borrowed.

Many of the older universities in Germany have museum-like collections with plant and animal specimens, and technological artifacts from the history of their university. The most famous and oldest university museum is in Heidelberg. Marburg and Halle have important university museums and with them, the Berlin Humboldt-University collection are all famous in medicine and science. Altogether there are 700 collections existing at universities with significant objects of science, technology, medicine, history, and art.^[47]

Historical, Anthropological, and Archeological Museums

Besides the large national institutions, there are more than 2000 historical museums and historical sites in Germany and many of these local museums were founded during the Nazi regime. During recent years important new themes have developed for these museums such as

memory-culture (Erinnerungskultur), oral history, and multicultural collections. Local history museums are key to the historical understanding of the people, and now the museums exploring the oppression of the Nazi period are becoming important. Some of these museums consist of historical parks to explore the history of early settlements, old housing, and economy. Often positioned in the countryside, these outdoor museums have special functions in supporting regional tourism.

There are many historical sites associated with Germany's world-famous authors, philosophers, artists, and other historical personages. There are museum houses of Goethe and Schiller not only in Weimar but also in the towns of their birth, Frankfurt and Marbach, and the same is true for Bertold Brecht in Augsburg (his birthplace) and in Berlin where he lived and worked for so long.

Archeological finds in Germany cover a wide range of periods, starting with the Homo Neanderthalensis in the Neanderthal near Düsseldorf (130,000 years ago). The Hedeby Viking Museum, (eighth to eleventh century), and artifacts from the Roman era found along the Rhine and Mosel and exhibited in archeological sites and museums from Cologne to Trier, from Xanten to Mainz. Site museum also represent the complex history of German duchies and small kingdoms. From the Middle Ages to the Renaissance, from the Baroque to a new Gothic style all types of castles can be visited. Many castles and palaces are regional museums and there are special tours along the Rhine to visit the numerous, beautiful castles on the mountains there. More than 80 scenic holiday routes throughout Germany are integrating local museums into their proposed itineraries; these include museums related to fairy tales, toys, windmills, or asparagus, just to name a few.

Special museum sites have developed in Germany to honor the victims of the crimes of Nazi Terror—the Gedenkstätten (=the memorial sites of the Holocaust). They are more than a normal holocaust museum as they commemorate the site, where the Jews, the Communists, and the Roma were murdered. Many of the buildings of these sites still exist and show the brutality of that time. All these memorial sites have many activities for students and host regular lectures for the public.

ZOOS AND BOTANICAL GARDENS

In Germany, zoos and botanical gardens are not counted in the statistics of German museums.^[48] Nevertheless, Germany has many zoos and the Berlin Zoo has the most animals and species of any zoo in the world. *Berlin Zoologischer Garten*, founded in 1841, has 13,722 animals of 1388 species and has now been combined with the Tierpark Berlin-Friedrichsfelde in former East Berlin, founded in 1954 with 7955 animals of 976 species.^[49] Important zoos are Hagenbeck in Hamburg, Hellabrunn

in Munich, Wilhelm in Stuttgart and the Cologne Zoo. Altogether, there are more than 750 zoos listed in the German Zoo Database.^[50]

Botanical gardens in Germany have existed since the sixteenth century. Often such gardens developed from former monastery gardens and were later affiliated with the neighboring university (as in Leipzig, 1539). Today, more than 90 botanical gardens offer great attractions. The *Berlin Botanischer Garten and Botanisches Museum* (=Berlin Botanical Gardens and Botanical Museum) with more than 22,000 plants is the third biggest botanical garden of the world. Every 2 years a new botanical garden is founded in Germany as the result of the Bundesgartenschau, a biannual Federal horticulture show.

DIGITAL MUSEUM EXHIBITS AND SERVICES

Creation of digital museums in Germany is just starting. As more and more museums have the documentation of their collections accessible in digital form, the museums are starting to put these materials online. Digital museums often just mean that the list of objects can be found on the museum Web site. Nevertheless, a few museums have scanned their objects and put these up in the Web. The German Historical Museum in Berlin has already digitized 250,000 items which are searchable via Internet.^[51] Big museums like the German Historical Museums are in the forefront in developing virtual exhibitions. Together with Bonn, they are part of the LEMO, the Living Museum Online, a collection of Germany's history with interesting historical multimedia files from 1871 up to the present.^[52] The Gemäldegalerie Dresden is one of the few German museums represented in virtual reality with attractive explanations accompanying its objects online. German museums have started a Web presentation to concentrate their virtual activities. This Virtual Library Museum has been created by the German Museum Association in cooperation with International Council of Museums (ICOM) Germany and the Museum Institute, and cosponsored by the Historisches Centrum Hagen. Thus, all museums in Germany with virtual activities, documentation, and Web sites are listed here.^[53]

Museology as a Discipline and Profession

In November 2007, a very important conference on museum research took place in Berlin, sponsored by the Volkswagenstiftung—Volkswagen Foundation. More than 4000 museums were asked to respond to a questionnaire on research in museums. Research is an important part of museum activities and in 2008, as a follow up, the Volkswagen Foundation launched an initiative of research in museums with support of doctorate and post doctorate research in middle-sized museums, international research networking of curator; they also provided funds for

making more information about research in museums available to the public. Major museums have research agendas, as has the Museum of Natural Science in Berlin. Currently, this research concentrate on six different research lines including biodiversity, evolution, impact research, and research history.

Education for Curatorship and Museum Administration

More than 50 universities and universities of applied science offer a wide range of courses from museology in Leipzig to museum studies in Berlin, and they teach practical knowledge of how to run a museum. Cultural management and museum paedagogics (museum education) are also research fields at some universities. Nevertheless, many museum curators have studied art history or have other traditional university degrees before the Bologna process in 1999 introduced the bachelor and master degrees in Germany. New developments in this field can be expected.

The “Voluntariat,” (a museum assistant in German museums) is a 2 year, low-paid training period at an institution, which is prerequisite to gain a permanent position in one of the museums. After finishing a university master’s degree or doctorate, one can apply for a “voluntariat” at a museum. In contrast to training for librarianship, there is no clear museology curriculum, but only on-the-job training for these museum specialists. Therefore in 2007, a group was founded by the museum associations to establish regulations and standards for training museum assistants.

Professional Associations

The Deutscher Museumsbund (=German Museums Association), founded in 1917, is the premier organization for museums and its membership includes both institutions and individuals. The Association works closely with the Institute of Museum Research in Berlin which produces the German museum statistics each year and supports museum research. The statistics on museums only include museums that are open to the public and not commercial. The Institute is also the home of the central special library on museology in Germany. It was founded in 1979 in response to similar developments in the German Democratic Republic. The Museumsbund also cooperates with the National Committee of the International Council of Museums—ICOM Deutschland which supports international exchange programs. There is no strong cooperation between the regional associations of the German Museum Association. The most important meeting is an annual conference.

Small- and middle-sized museums are supported by some institutions in the Länder, which give advise and help. In some Länder like Bavaria and Baden-

Württemberg these are public institutions, in other Länder like Lower Saxony or Brandenburg, the Museum Association has this task. Therefore the regional museum organizations are important in the Länder.

Key Contemporary Issues

The museum associations have established various projects and research groups. The educational task of museums has been one of the main topics in German museum discussions for more than 30 years. Museum education programs are aimed at children as well as at adults, and their goal is to inform and support understanding of the museum objects. These discussions have focused on methods of integrating museum education: either as supplementary to the exhibition or as an integral part of the exhibition concept. There is a special association for museums’ educational tasks. In cooperation between different partners some projects like <http://www.schule-museum.de>^[54] have developed very successfully.

Other contemporary issues under discussion are visitor research, marketing museums, and managing volunteers. A lot of research is being done on conservation and restoration in museums and there is an active exchange of knowledge on disaster prevention. Research on museum visitors is a one of the most important aspects of modern museology in order to optimize exhibition content and location, and to analyze the impact of the museums. A working group on volunteers in museums has published a position paper and the discussion shows different views and activities with volunteers. For several years, the multicultural aspect of museum work has produced discussion and new activities now focus on the history of the Germany’s immigrants in the local Heimatmuseums. The “Long Museum Nights” with museums being open without fees for the entire night first started in Berlin in 1997 and has become a very attractive event twice a year and a role model for other museum nights all over Germany.

In February 2006, the German Museum Association published standards for museums. These are not rigid regulations, but important guidelines to assist in developing individual activities along these standards. The German view on museums is determined by these regulations set out by the Museumsbund: professional supervision with adequate support for researchers and scientific specialists. Another basic principle: The original has to be placed in the center of all exhibitions.

CONCLUSION

Convergence and cooperation among the various information institutions in Germany have not been developed extensively and there are few strong ties between them. Libraries, archives, and museums have their specialized standards, different software tools, and different training

programs. It is difficult to merge databases and information.

Provenance Research, a common topic for museums, archives, and libraries, is currently gaining importance, as during World War II many collections were lost, confiscated or displaced. The Nazis seized art collections and libraries from Jewish civilians before they were deported to concentration camps. Many of these objects were placed in museums and libraries. After more than 50 years it is extremely important to clear up the “smudges” in ownership, to learn more about the lost and looted art, and to support the Washington Declaration from 1998 about restitution, which has also been reinforced by a declaration by the government of the Federal Republic of Germany. Libraries, archives, and museums are working together to identify Nazi-confiscated cultural property and place it into <http://www.lostart.de>, the Internet Portal of the Koordinierungsstelle für Kulturgutverluste (=the coordination office for lost cultural property) in Magdeburg.^[55]

One model of cooperation is the BAM-Portal, a Web portal for libraries, archives, and museums, which helps libraries, archives, and museum to coordinate digital projects. This includes European digital projects like EUROPEANA which include Germany's cultural heritage at the European level. In future digitization will play a greater role in convergence between libraries archives and museums. Nestor,^[56] the German network of expertise in digital long-term preservation, will become an important cooperation for libraries, archives, and museums and their future in the digital age.

Global Open Knowledgebase

Kristen Wilson

North Carolina State University Libraries, Raleigh, North Carolina, U.S.A.

Abstract

The Global Open Knowledgebase (GOKb) is a project to build an open-data, community-managed knowledge base that describes academic publications as they appear in the supply chain. GOKb was designed and implemented by the Quali Open Library Environment founding partners and Jisc Collections, and is maintained by the Open Library Environment. This entry describes the history of the project and the core functionality of the GOKb service.

INTRODUCTION

This entry will introduce readers to the Global Open Knowledgebase (GOKb) project, including project history and core functionality.

GOKb is an open, community-managed repository of metadata describing electronic resources as they are represented with the academic publishing supply chain. Like existing commercial knowledge bases, GOKb includes standard metadata elements describing the components that support the marketing, sale, purchase, and hosting of electronic resources. Through GOKb, users can acquire information about the titles sold by a particular publisher, the package grouping used by the publisher for sales purposes, and the access platforms used to make resources available to library customers and their end users.

Founded in 2012, GOKb began a project of the Quali Open Library Environment (OLE) founding partners, including North Carolina State University (NCSU), Indiana University, the University of Florida, Lehigh University, Duke University, the University of Chicago, the University of Maryland, the University of Michigan, and the University of Pennsylvania; and Jisc of the United Kingdom. NCSU served as the lead school for the project. As of 2016, GOKb continues to be supported by OLE.

FOUNDING AND BACKGROUND

The GOKb project was initially conceived as a way to provide an integrated knowledge base for Quali OLE, a community-source library services platform (LSP) that began development in 2011. During the initial planning for GOKb, the organizers recognized that an open, global knowledge base could serve the needs of similar projects in addition to OLE. Knowledge Base Plus (KB+), an electronic resources management service provided by Jisc Collections of the United Kingdom, was already in development at the time and shared a need for a central

repository of data describing the packages and titles managed by its users. KB+ was recruited as a partner in the development of GOKb and began collaborating closely in the initial planning phases of the project.

In 2012, the Andrew W. Mellon Foundation awarded the NCSU Libraries a \$499,000 grant to serve as the lead institution in the development of GOKb. Quali OLE and Jisc were named as partners in the project.^[1] This grant funded the first phase of GOKb development, which ran through September 2014. Phase 1 included data model design, the development of a web-based interface for browsing and editing data, and the development of a rules-based tool for validation and data ingest.

At the conclusion of the Phase 1 grant funding period, the GOKb project launched a public preview designed to demonstrate the latest version of the GOKb software, including the web application, API, and co-reference service. The preview also contained a small amount of seed data to illustrate the different record types found within the system. Additional data was added throughout Phase 2 of the project. The preview period was intended as a demonstration of GOKb's potential, with the intent of attracting additional partners to the project.^[2]

The Mellon Foundation awarded a \$333,000 grant to the NCSU Libraries in 2014 for additional development of GOKb. This funding period ran through March 2016 and supported new development directions for GOKb including expansion of the data model to support e-books, implementation of linked data, and exploration of intersections with other projects addressing open access and open data in scholarly communication.^[3]

The primary governing body of GOKb is a steering committee that contains representatives from OLE, NCSU, and other stakeholder groups. The steering committee is responsible for the operations of the GOKb project and has joint reporting responsibility to the OLE Board.^[4] The GOKb project has one full-time staff position, the GOKb editor, which reports to the principal investigator of the project based at NCSU Libraries.

RELATIONSHIP WITH OLE AND JISC

The GOKb development team worked closely with OLE participants to design a data model and tools that would support the management of electronic resources within the OLE LSP. These efforts included the development of an API that would allow OLE to consume data from GOKb and receive updates when changes were made at the global level. The benefits of the planned integration between these two systems included the ability to create local records linked to their global counterparts via a canonical identifier and to manage changes to these entities through a management dashboard. As changes were made within OLE, they could be communicated back to GOKb and shared across all users of the system.

In mid-2016, the OLE partners decided to cease development of the existing OLE LSP and proposed e-resource features, including integration with GOKb. Also in 2016, OLE became a participant in FOLIO, a new community collaboration to develop an open source LSP. Other FOLIO partners include EBSCO and Index Data. While GOKb is not explicitly part of the FOLIO roadmap at this time, the project partners have put forth a stated goal of integration with multiple knowledge bases, and GOKb remains a candidate for inclusion in the project.

GOKb also maintained a relationship with Jisc throughout most of its early development. At the time of GOKb's initial request for funding, Jisc had already begun development of the KB+ project, which aimed to create a knowledge base describing journal collections negotiated by university libraries within the United Kingdom. Leadership from both projects recognized the similarity of the data being collected and concluded that each could enhance the progress and quality of the overall effort through collaboration [5]. GOKb and KB+ functional experts and developers worked together to create a shared data model for both projects. KB+ originally intended to shift the management of its knowledge base data from a local environment to GOKb. However, changes to the mission and distribution model of KB+ prevented the change from being implemented.

The GOKb project remains closely aligned with OLE in its governance. While GOKb operated semi-independently throughout the grant-funded phases of the project, once the funding expired, its governance was folded more closely into the OLE project to ensure long-term sustainability. The OLE project partners provide ongoing financial support for GOKb through partner dues. Financial contributions primarily support the continuation of the GOKb editor position, which is part of the OLE core team of staff.

CORE FEATURES OF GOKB

GOKb expands on the traditional knowledge base feature set in a number of ways. While existing knowledge bases

have offered a snapshot of electronic resources that exist at the current moment in time, GOKb's data model will include an expanded set of attributes to facilitate tracking of changes. GOKb can store information about changes to works, such as a bibliographic title change or a transfer between publishers. Additionally, the system uses a series of status to track information about resources that have ceased or are not yet available, thus allowing users to see how the contents of a package have or will change over the years it is offered for sale.^[6]

Another key component of GOKb is its open-data model. GOKb's data are freely available under a Creative Commons 0 license, which allows use by anyone for any purpose without attribution. This openness means that GOKb's data can be consumed by its official partners, as well as any interested party, including commercial entities. The GOKb project has cited several benefits to the open-data approach, including the potential to partner with a wide variety of institutions and corporations, as well as the benefits of separating data from software.^[6] By making well-structured, accurate metadata freely available across the industry, GOKb hopes to see adoption not just by library partners but also by academic publishers and library vendors, who can use GOKb's service to improve their own products.

The use of a community contribution model for data sourcing and maintenance is another differentiator for GOKb. Discussions with partners, as well as a number of potential collaborators internationally, have highlighted the similar problems that institutions face when it comes to managing knowledge base data.^[5] Users from across these institutions spend time on tasks such as reconciling publisher- and vendor-provided title lists against knowledge base data and investigating title changes. These activities commonly result in customers informing their commercial knowledge base vendors of a series of changes, which are then incorporated into that vendor's product.^[2] By harnessing these efforts and capturing the outcome in a freely available, centralized environment, the GOKb project aims to increase the impact of this work by making it available across the entire community of libraries and vendors.

It is also important to note that GOKb differs from the traditional knowledge base in two major ways. First, GOKb is not a discovery knowledge base; rather, it is intended to support that management of electronic resource purchasing and licensing operations. GOKb does not support discovery tools such as a link resolver, MARC record service, or unified search index. This means that GOKb is not intended as a replacement for those products that rely on vended knowledge bases. Second, GOKb is not an environment for users to store information about their local entitlements. It exists purely as a data repository. It will be the role of partner systems to provide an interface that can consume GOKb's data and allow users to create local variations on the data.

DATA MODEL AND DATA ELEMENTS

GOKb uses a bill of materials data model to represent the elements that make up the e-resources landscape. This model represents the raw materials needed to create an end product. In the bill of materials model, raw materials are called “components” and the end product is a “combination” of those components.^[7] In GOKb, for example, one of the core components is the title. Titles can be combined to form packages. A combination like a package can then be linked to another component, such as an organization, to create a new combination. The advantage of this model is that its flexibility makes it extensible. Components and combinations can always be linked in new ways to meet the changing landscape. If, for instance, GOKb was expanded to include article-level information, articles could be added as a new type of component, which could then be linked together to form a journal combination.^[6]

The core components that make up the GOKb data model are titles, packages, platforms, and organizations. The title component describes a journal or other resource at the work level. Title history information, such as publication dates, current and past publishers, and relationships to other titles, are also stored on the title component (see Fig. 1). Packages represent groups of titles that are commonly sold together for a set price, while platforms represent the websites where those titles and packages are hosted. A unique feature of GOKb is a combination of components called the title instance package platform, or TIPP. The TIPP goes beyond simple bibliographic description to represent a resource as it is purchased and managed by a library. By creating an entity to represent

this combination, GOKb provides a place to store meta-data describing salable units. The TIPP record also allows GOKb to assign an identifier to this important concept as well as to link it to other components and make machine-readable statements about it.

Organization records can be linked to any component type to provide additional detail. Organizations can play different roles depending on their context. For example, the organization Springer can be related to a title in the role of publisher, while it may also be related to a platform in the role of platform provider.^[2]

METHODS OF ACCESS

Web Application

The GOKb web application provides a public interface for browsing and searching of GOKb data, as well as an editing tool for project partners. Users can navigate the various components found in the knowledge base and explore combinations using links between records. The data in GOKb may provide general value as a reference tool, supplying such information as bibliographic metadata, details of changes over time, lists of available packages and their contents, and basic access information.

For project partners, the web application provides additional functionality, including the ability to edit the data found in most fields. This allows for easy correction of isolated errors or basic updates. The web application also allows users to perform a series of more complex actions, including title changes and transfers. Finally,

Fig. 1 A title record in GOKb.

GOKb Validation Status

- DateFirstPackageIssue**
One or more rows contains invalid dates in the column "DateFirstPackageIssue".
- KSARTEmbargo**
Data in the column "KSARTEmbargo" must follow the KSART guidelines for an embargo.
- DateLastPackageIssue**
One or more rows contains invalid dates in the column "DateLastPackageIssue".
- CoverageDepth**
Import does not specify an CoverageDepth column.
- title.oastatus**
Import does not specify an title.oastatus column.
- title.imprint**
Import does not specify an title.imprint column.
- PrimaryTIP**
Import does not specify an PrimaryTIP column.

Fig. 2 The OpenRefine custom extension for GOKb.

the application contains a lightweight problem tracking system that allows users to create review tasks and assign them to themselves or other users. Review tasks are also generated automatically when new data ingested into GOKb conflicts with existing data in the knowledge base.

OpenRefine

GOKb uses an open-source data manipulation tool called OpenRefine to allow population of the knowledge base with large, externally sourced data sets. Through OpenRefine and a custom GOKb extension, users can validate data and upload it to the knowledge base. The GOKb extension applies a set of rules designed to help users modify data so that it complies with GOKb's data specification. Common transformations include renaming columns, adding missing information, reformatting dates and abbreviations, and resolving data conflicts like duplicate ISSNs (see Fig. 2). The GOKb extension for OpenRefine also provides a collaborative workspace and version control features, allowing users to share project files.

API

GOKb offers an API that allows external services to extract data from GOKb and credentialed users to contribute changes back to the knowledge base. The API uses the OAI-PMH protocol.^[5]

Co-Reference Service

Many of the components in GOKb can support multiple identifiers. GOKb can collect and store identifiers

across namespaces that describe roughly equivalent concepts. On the title record for example, GOKb may store title identifiers that include the ISSN and e-ISSN, DOI, and publisher's proprietary identifier. These identifiers are linked together through the title component, which is assigned a GOKb identifier. The co-reference service provides a crosswalk between identifiers by allowing users to search for any identifier and return a list of all identifiers associated with the same component. The co-reference service is not a registry and makes no assertions about the correctness of any of the identifiers stored within GOKb. The co-reference service can be accessed through the GOKb web application (see Fig. 3) or through the API using a JSON or XML query.^[5]

CONCLUSION

The development of GOKb has established the principles and structure needed to create and provide a comprehensive, open repository of key metadata about scholarly publications. These core components include a data model to support the description of electronic resources, both in the present moment and as they change over time, multiple modes of access to support human and consumption; and a community of invested partners who can contribute expertise and resources to the collection and maintenance of knowledge base data. The work on GOKb to date serves as a strong proof of concept for the technical feasibility of and community interest in an open knowledge base. Future efforts for GOKb will include evaluating the potential for the project to increase its scale and continue building community interest.

James Church

University Libraries, University of California, Berkeley, Berkeley, California, U.S.A.

Abstract

Collecting and managing government information in the twenty-first century is a challenge to most libraries and librarians. Historically, government documents were difficult to collect and manage in a print environment; yet while the digital transformation of information makes some government publications more available, at the same time, the Internet allows for valuable content to be more readily removed. This entry examines government information in all its forms and formats to offer a comprehensive assessment of issues involved in the development and management of government information (publications, documents, etc.) collections in print, electronic, and digital formats. The goal of this entry is to explore how nineteenth-century bibliographic description shaped the twenty-first-century government information society and this particular field of librarianship is paving the way for future developers of collections. The first three sections of this essay focus on U.S. documents at the federal, state, and local levels; The fourth section concerns international publications. Each section will detail the relevant history and strategies for developing and managing a viable, fluid government publications collection.

INTRODUCTION

What is a government document? It is informational matter created by a government. The U.S. government defines it as any informational matter printed at government expense or as required by law, 44 USC 1901 (2012). Government documents librarianship is a field that is guided by this U.S. law. Government documents collections include materials found in libraries including digital objects, monographs, serials, periodicals, maps, technical reports, ephemera, kits, etc. The main difference is they emanate from government bodies. All government bodies produce documents. Libraries of all kinds (academic, public, school, and special) collect government documents. When most people think of government documents, images of unending pages of census figures and appropriation hearings come to mind, but few consider that one of the most popular government documents is the re-release of the Warren Commission Report. Think you are smarter than an 8th grade civics student? Then, you should check out the Civics Quiz on the Government Book Talk blog at <http://govbooktalk.gpo.gov/?s=civics+quiz>.

In this entry, the phrase “government documents” is used interchangeably with “government publications” and “government information.” The form or format of a government document does not negate the laws that require printing or dissemination. This entry examines collecting

and managing government documents at the federal, state, local, and international levels of government. A bibliography along with relevant websites is included at the end. Please note, as the field changes, so too does this bibliography.

FEDERAL PUBLICATIONS

Historical Foundations

From the time Congress first started publishing the *Journal* as required by the *Constitution of the United States*, American libraries were interested in collecting government documents. Publications issued by the government cover all manner of subjects and disciplines ranging from weather reports and train schedules to budget analysis, judicial decisions, and administrative laws. Although the interest still exists, government documents are still as mysterious today as they were in 1860 when the Government Printing Office (GPO) was created to counter the growing corruption in printing contracts, the advent of newspaper patronage, and concerns about the cost of official publication. The foundation for what is today known as Federal Depository Library Program (FDLP) originated in the first 12 Congresses and later became centralized in the Printing Act of 1895 (28 Stat. 601) along with the

Office of the Superintendent of Documents.^[1] First, this act developed a federal depository library program as a means to consolidate printing, publishing, distribution, and dissemination of official government publications. Second, the act led to the development of a central collection of government documents by Adelaide Hasse, the inventor of the Superintendent of Documents (SuDocs) classification scheme. Ms Hasse began developing this classification scheme when she worked at the Los Angeles Public Library and later took her skills to Washington to begin developing a documents library at the GPO between 1895 and 1903.^[2] Based on the principle of provenance, or issuing agency, rather than a subject-based scheme, it is an alphanumeric organization based on the status of the government agency. Her creation of a comprehensive list of publications from the Department of Agriculture was the first of many tools created to build, develop, and maintain library collections of government documents including the development of the *Monthly Catalog of United States Government Publications*, the basic finding tool for federal publication until the advent of the Internet. This act firmly established government printing, publishing, dissemination, and distribution of materials as *functions of both* the Legislative and Executive branches of government. Prior to the act, all materials were published at the express request of Congress and many libraries tried to develop their government collections based upon lists of publications rather than an overall strategy catering to local need. As the country grew, so did the government, and soon the Executive branch took over as the main producer of government information. One of the provisions of the Printing Act of 1895 was to create a depository library system to ensure all citizens had access to their government's activities via publication. *The fundamental purpose of the Federal Depository Library Program is to ensure that all Americans have permanent public access to their government's information regardless of form or format.*

The next major change to the FDLP was the Depository Library Act of 1962 (76 Stat. 352), which enhanced access to depository libraries by expanding the number of depository libraries per state and creating two types of depositories: regionals, which are required to keep permanently all government publications disseminated through the FDLP, and selectives, which may pick and choose which kinds of publications to house plus may dispose after 5 years. For a short history of the program, please see http://www.access.gpo.gov/su_docs/fdlp/history/macgilvray.html.

Today, the FDLP is a partnership between the GPO and 1,175 libraries representing most Congressional districts across the nation (see Table 1). GPO prints, digitizes, and disseminates government information products utilizing all information technologies available. Additionally, this agency is recognized as the authority for the bibliographic control, cataloging, and classification for all federal government publication. The GPO serves as a model for state

Table 1

Library Type	Number	Percent
Academic General	627	54%
Public Library	180	16%
Academic, Law Library	150	13%
Academic, Community College	56	5%
State Library	39	3%
Federal Agency Library	37	3%
Highest State Court Library	37	3%
Federal Court Library	11	1%
Special Library	14	1%
Service Academy	4	0%
TOTAL	1155	100%

Note: Special thanks to the U.S. Government Printing Office. Data accurate as of March 30, 2016.

and international government depository programs. Building upon both a history and tradition of public service, these depository programs are still germane in an electronic environment. While the publications themselves may not be tangible, knowledge of the interconnectedness of governments, how agencies work or in some cases do not work together and why government publications are developed differently than other information resources are all examples of why this field in librarianship is thriving. For additional information about the FDLP, please see <http://www.fdlp.gov/>.

Throughout its history, the U.S. government embraced technology. GPO frequently was in the forefront in implementing new technologies from handset to machine set typesetting to digitization and everything in between. In January 2014, Public Printer Davita Vance-Cook led the move to change the name of the 154-year printing establishment, Government Printing Office to the Government Publishing Office, in an effort to better describe the digital transformation beginning with Public Law 104-30. She testified: "It's time for our name to catch up with who we are and what we do. It's time for a new name for the digital age."

Transforming Government Information

In the introduction to the textbook *Fundamentals of Government Information*, the authors discuss the transition of the FDLP and the need for permanent public access to government information eloquently stating:

The formats of government information have transitioned quickly in recent years. The print era evolved to the web era; then HTML and PDF documents became blogs and wikis, which became videos, which became ever-evolving websites . . . As revolutionary as this electronic migration has been for government information, many aspects of depository libraries and services are less changed.^[3]

The information revolution taking place is changing the very nature of American society. Fondly called the

“Information Age,” the twenty-first century is a time where every American is overwhelmed with too much content but little organization of information. The growth and permeation of the social media everywhere means that more information is available without the filters provided by proofreaders, editors, reviewers, etc., which was prevalent in the era of print publication. The digital divide of the previous decade is not the same concern it once was; instead, libraries are faced with a three-pronged dilemma of providing access to born digital information, preserving tangible collections, and creating safe digital spaces for users.

Aside from depository library programs, collecting government information is difficult regardless of where it is housed in a library, on a server, or in the cloud. Many librarians still comb the “media” for stories about government-funded studies, reports, proposed legislation, guidelines, and/or regulations to find what is most germane for their collection, regardless of whether they are available in electronic or tangible formats. The advent of digital information not only made finding information easier but also made removal of information just as simple. In fact, most library research conducted today is focused on the policies of electronic creation, dissemination, and preservation of government information. Current writing focuses on the sheer volume and integrity of electronic information. And yet, digital information is not immune to the guidelines limiting how it should be distributed via social media.^[4] It is up to those librarians to work collaboratively in building permanent collections.

Congress enacted additional legislation such as the Government Printing Office Electronic Information Access Enhancement Act of 1993 (107 Stat 112) and the E-Government Act (116 Stat 2899) to further provide access to government information in electronic form, but neither piece of legislation provided GPO the same authority over electronic information produced by the U.S. government as print distribution of depository materials. There remain many questions of access and equity. This division is examined in detail.^[5] The question remains with collecting and managing electronic information. “Who is responsible for permanent public access to electronic and digital content?” This question permeates depository librarianship in the early twenty-first century.

Depository Libraries and Management

As mentioned earlier, government information permeates society unlike other publications. Whether it is interest in the Iraq War or reading the “Starr Report” or filing a tax form, more and more Americans use government information more readily than ever. During the age of print, government publications followed a fairly narrow hierarchy for publication. It was mainly due to this form that the bibliographic control and organization of government

documents is based on issuing agency rather than on subject. Thus, the SuDocs classification scheme became the primary means to organize print collections. This classification scheme further allowed for the FDLP to develop its mission and goals: to be the primary means of government information dissemination and preservation. Several print indexes and abstracts were developed in order to provide access to government publication. Building upon Adelaide Haase’s list of USDA publications, bibliographic tools such as *The Monthly Catalog of U.S. Government Publications*, *GRA&I (Government Reports Announcements & Index)*, *ERA (Energy Resources Abstracts)*, and *RIE (Resources in Education)*, plus the many products from the Congressional Research Service were developed in order to provide bibliographic access to government publications. While online equivalents of these print reference resources exist, they do not provide the same level of bibliographic control simply because the online equivalent works quite differently from the print. However, the GPO continues to work with their partners in the FDLP to use newer technologies to enhance access to government information and provide permanency of this information. This program is still one enduring example of how government works well in keeping the citizenry informed.

The success of the FDLP led to the creation of other depository programs including state, local, international, and foreign programs based upon a government providing copies of its public documents to libraries in exchange for those libraries housing the material, providing access to these materials, and in many cases, providing experts to assist the citizens in locating the information. This principle is the basic strategy librarians use when developing government publication collections. Not so long ago, this strategy of having agencies send materials directly through the GPO was a reasonable method for developing a depository collection. The U.S. Census Bureau and Patents & Trademark Office (PTO) both created successful depository programs after the initial success of the FDLP. Each agency looked at libraries as places where citizens could obtain specialized agency information.^[6] In fact, the PTO Depository Program was more successful in some ways since the PTO instituted a plan to ensure that patent librarians were trained by the experts employed in the Office. Detailed descriptions of the various depository programs are widely discussed in the literature, but no better sources exist than the works of Laurence F. Schmeckebier, including his agency histories and his overview of government publications. While his books are nearing their century mark, their importance is still as great as when first published, especially given the challenges of managing government publications in an electronic environment.

The complexity of the modern world, coupled with ever-changing and increasing information policies and technologies, makes the dissemination of government information more challenging. Even before the beginning

of printing, governments made policies to control the flow of information.

Information Policy

Jaeger defines information policy as “the combination of laws, regulations, rules, and guidelines that steer the creation, management, and use of information.” The Internet transformed the entire way society views and uses information thus public policy on information is more on the mind of legislators and administrations. It is common knowledge that whoever controls the flow of information, controls the government, hence the fight within governments regarding the release of information.^[7] Each session of Congress deals with more issues related to information, from freedom of information to protections of intellectual property; security and civil rights; and personal privacy versus the government’s need for personally identifiable information.

One overwhelming challenge early in the depository process was when government agencies did not furnish copies of their publications to the GPO, leading to what is known as “fugitive documents” or those publications that belong in the program by law, but are not included, for various reasons internal to particular agencies. This same problem is echoed today by those agencies that continue to produce digital documents but provide no mechanism for digital preservation, thus denying permanent public access. Public access to government information is considered by many to be a right of citizenship, although there is no law or official policy enforcing that right. An example of this was seen in President Obama’s revocation of EO 13233 by his own executive order.^[8] This Executive Order offered the president to extend executive privilege to other members of the Executive Branch including appointed officials within the Cabinet or senior staff members. Another proviso of EO 13233 allowed a president to exert this privilege at any time over any document of any president. By rescinding this Executive Order, President Obama restored Congress’ original intent of the law limiting the time allowed for the privilege and who can use this privilege. This example ensures the people the right to know what the president is doing. The principles of our society are built on a democratic framework that requires citizens to be informed of their government’s actions. The *Constitution of the United States* outlines how that framework will work, including a provision that requires a journal be kept of proceedings and actions.

The importance of information policy and e-government is discussed in other chapters in this encyclopedia. As more scholars analyze these policies as part of their study, government publications become more preeminent in their work and analysis. The need for collecting and managing this material is still a vital role for librarians and administrators. While the federal government provides an overarching view of information policy, states and local

governments each have their own opportunities and challenges in developing their information policies.^[9]

STATE PUBLICATIONS

The formation of territories and state governments was authorized by acts that are included with other laws in the *United State Statutes at Large* and may also be found online at some individual state Web portals.^[10] State government impacts daily life through taxes, education, public safety, economic growth, laws, and regulations. State government agencies communicate with the public in a number of ways. For some agencies, educating the public is an important part of their mission. Service-oriented agencies such as departments of health and human services have historically produced a large number of public documents. A public document, loosely defined, is any informational matter, regardless of format, which is produced for public distribution by state agencies or state institutions of higher learning. Vital statistics such as number of births, and number of and causes of deaths, are examples of public information found in state documents. Other examples include schedules of state elections, statistics about public schools, and instructions for acquiring a driver’s license.

While the FDLP provides leadership, best practices, and regulations for federal publications, there is no central governing unit to manage access to state publications. Individual states are left to their own devices to develop, implement, and manage the lifecycle of state-produced public information. Using the FDLP as a model, many states have established state depository library programs.

In most cases, it is the state library or an equivalent agency that administers the state depository library program. Typically, depository programs are charged by their respective legislatures with collecting, indexing, distributing, and preserving state public documents.

Depository programs collect state documents by obtaining physical copies from state agencies or by acquiring and archiving electronic copies. Electronic copies are most commonly harvested from the web, received by e-mail, or uploaded by state agencies directly to a database or repository. Even though most depository laws require agency compliance, many agencies ignore them or selectively comply, resulting in an incomplete collection. Because state library resources are limited, efforts are typically made to collect at least core materials, items that are deemed the most important to preserve and make accessible. Items collected are commonly classified using a classification scheme developed specifically for that state’s publications—though some programs do use Library of Congress (LC) or Dewey Decimal numbers—and recorded in a catalog, index, and/or list. Cataloging records are usually made available in the state library’s online catalog and may or may not be added to a national

bibliographic database such as *WorldCat*. Shipping lists and monthly checklists, organized lists of items received since the last listing, are often used to notify participants about the arrival of new items into the depository program.

Physical publications are typically distributed to a network of depository libraries throughout the state and often to the LC as well. Like state agencies, depository libraries are required to comply with the laws, rules, and regulations governing the depository program. They provide space for the collection, staffing to assist the public with finding state publications, and most often have to retain depository publications for a certain number of years and obtain permission before disposing of them. In some programs, depository libraries are required to make digital publications available by including bibliographic records with live links in their online catalogs. Archived copies of electronic publications are generally made available online via links in the state library's catalog, or in a dedicated, searchable state documents database or repository (i.e., *Iowa Publications Online* at <http://publications.iowa.gov/>). Collectively, the libraries in the network attempt to preserve access to state publications in perpetuity.

For a more detailed overview of key state publications and state depository library programs, consult Lori Smith and others' *Tapping State Government Information Sources* published in 2003.^[11] In part one, Smith discusses general sources covering all 50 states, including publications that are both state government produced and commercially produced. Part two contains a chapter for each individual state with information regarding its depository system, as well as useful addresses and telephone numbers, indexes to state publications, essential titles, pertinent commercial publications, and its Web portal. For an overview of efforts to archive and preserve federal, state, and local digital documents, see *Managing Electronic Government Information in Libraries: Issues and Practices*.^[12]

Beyond print publications and their electronic siblings, state governments provide a wealth of additional information and services online. Technology and electronic resources have led to the rise of e-government. According to a 2007 report from the National Association of State Chief Information Officers (NASCIO), the number of citizens using the Internet to access state agency information and transact business was increasing, and the sophistication of state government Web portals was improving.^[13] In 2010, a Pew Research Internet Project publication reported that 82% of Internet users had accessed government information or utilized a government service online.^[14] A 2011 report from the Pew Research Internet Project noted that the Knight Commission on the Information Needs of Communities in a Democracy had found that two key indicators of a successful "community information system" were "A vibrant public library, or other public center for information that provides digital resources and professional assistance," and "A majority

of government information and services online, accessible through a central and easy to use portal."^[15]

Entities other than states have undertaken efforts at the national level to increase awareness of and access to state- and local-level documents. In 2007, the State and Local Documents Task Force (SLDTF) within the Government Documents Round Table (GODORT) of the American Library Association (ALA) created a "50 State Agency Database Registry" wiki.^[16] Volunteers adopt one or more states and maintain lists of databases that agencies in that particular state have built. The SLDTF wiki also offers, among other things, a list of links to state depository system Web pages and a list of librarians within each state who are willing to facilitate the exchange of state publications between libraries in different states.^[17]

The LC maintains Web pages featuring links to state and local government information from all 50 states.^[18] The Law Library of Congress also has a Web page with links to legal information for states and territories.^[19]

The LC collects state and local publications with a goal of building a research-level collection, which does not mean everything issued.^[20] Administrative reports, publications issued by state legislative and judicial branches, and planning and policy statements are examples of the types of items collected. With the exception of a few counties, the LC does not collect publications of U.S. counties. It does manage a comprehensive collection of cartographic materials for all counties, cities, and towns. Publications from a select number of major population centers are also actively collected.

From 1910 to 1994, the LC published the *Monthly Checklist of State Publications*.^[21] This publication was recognized as the national bibliography for U.S. state publications, but the demand for it decreased as online alternatives to it increased. Not everything in the *Checklist* was retained by the LC and not everything issued by a state was sent to the LC, resulting in an incomplete record of official state publications. Since the *Checklist* ceased, there has been no comprehensive bibliography to publications of the 50 states, but today a large part of what would have been included in the *Checklist* is available in Online Computer Library Center (OCLC) and Research Libraries Information Network (RLIN).

Many state checklists are now available online. In 1977, the SLDTF of ALA first approved guidelines for compiling and distributing state publications checklists.^[22] At that time, checklists were seen as necessary for bibliographic control. They are now useful as a current awareness tool. For more information about a particular state, check *StateList: the Electronic Source for State Publications Lists*, a project of the University of Illinois at Urbana-Champaign.^[23]

The *StateList* project uses the Web to make citizens aware of the publishing activities of state governments. In late 2014, a total of 37 states had provided links to state publication checklists and shipping lists currently available on the Internet.

The Center for Research Libraries (CRL) has acquired a collection of state documents that consists of the official publications of the legislative bodies, departments, and agencies of all 50 of the United States from the earliest period of state government through 1950. It also has holdings of legislative journals through 1990. Most of these materials are not in the CRL's catalog, but they are organized by state, by agency on the shelf. Additionally, the CRL has the pre-1951 *Records of the States of the United States of America: A Microfilm Compilation*.^[24]

This is currently a static collection with no concerted effort to develop it further.

When looking for historical information on state documents prior to 1908, refer to the four volume set covering 1899 to 1908 entitled *State Publications: A Provisional List of the Official Publications of the Several States of the United States from Their Organization*.^[25] For more state information prior to 1904, consult the multiple part set of the *Index of Economic Material in the Documents of the States of the United States* created between 1907 and 1922.^[26] The next major reference tool would be the *Manual on the Use of State Publications*.^[27] Published in 1940, it contained a detailed record of available bibliographic sources by state. In 1942, this was followed by *Government Document Bibliography in the United States and Elsewhere*, which included 20 pages of state bibliographic sources.^[28] This source remained the authoritative source on state document bibliography until 1975 when *Government Publications: A Guide to Bibliographic Tools* was published.^[29] Sixteen years later, in 1981, Margaret Lane's classic *State Publications and Depository Libraries: A Reference Handbook* was published.^[30] In part one, Lane provides the characteristics of depository library legislation. In part two, there is a state publications literature review followed by lists of bibliographic items that represents the largest portion of the book. In part three, 2–10 pages of information are provided for individual states.

The trend for the future is clearly toward more emphasis on digital information. Some depository programs are already predominantly electronic and nearly all have a strong digital component. Debate will continue about the long-term efficacy of electronic archives, and more focus will be placed on issues such as state government transparency, cybersecurity, open access, and big data. As with the FDLP, attention will inevitably turn toward digitizing the older publications housed in depository libraries and making those materials freely available online as well.

LOCAL DOCUMENTS

Local documents “are those materials issued by local governmental agencies and their subunits including municipalities, counties, townships, villages, special districts, school boards, park districts, and the like. Typical types of local documents include municipal codes, building

codes, zoning ordinances, annual reports of agencies, financial reports, minutes and proceedings of boards and committees, reports of committees and commissions, and any similar materials produced by governmental units.”^[31] One of the unique challenges for collecting local government documents is the plethora of local government entities, which leads to the lack of a central dissemination point. To provide some perspective on this challenge, according to the 2012 Census of Governments there are 90,107 governments in the United States, of which 90,056 were local governments. The breakdowns of these governments are

County: 3,031

Municipal: 19,519

Town or township: 16,360 special districts (school): 38,266

The state of Illinois alone has 6963 local governments.^[32]

While difficult to collect, local government publications provide unique information about the community—everything from urban life, to local health, to tourism. Local agencies may or may not keep publications for historical purposes, so preservation is a major concern for information originally available on government websites and in print. Like state and federal publications, another key challenge is learning about the existence of the document. Few local government agencies set up depository library programs, although some individual agencies will add a library to a mailing list. As more local documents move to the Internet, it becomes harder to track them, much less provide any kind of bibliographic control. According to Alexander Stille: “One of the great ironies of the information age is that, while the late twentieth century will undoubtedly record more data than have been recorded at any other time in history, it will also almost certainly lose more information than has been lost in any previous era.”^[33] The nature of the information published online also differs from that which was traditionally published in print.

It is estimated that more than 75 percent of local governments now maintain web sites. . . . Local government web sites tend to place an emphasis on showcasing the community's attractions to draw business and tourism to an area rather than featuring annual reports, in-depth statistical data, and full-text land use and planning documents. Annual budgets and summaries are sometimes posted, but it is rare to find more than the current year.^[34]

As mentioned previously, effective depository systems are virtually nonexistent at the local level of government. Nearby libraries may receive a small number of locally produced government publications, but may need to actively pursue their acquisition. Public libraries often collect local documents and typically view providing

access to them as a means of promoting and assisting citizens' involvement in government. The strength of local collections varies. There is a common practice to have open access to local documents that are organized by series such as "minutes" and "reports" and that have not been cataloged or added to a searchable database. To access information, it must first be findable, and publications that have not been cataloged or indexed are only minimally findable. A local government collection often includes names and contact information for agencies, departments, and elected officials. Other items collected may include the local municipal code, the annual budget for the city and/or county, and zoning ordinances. State and academic libraries, typically, are selective in regard to acquiring local-level publications.

For a more detailed overview of this topic, see *Local and Regional Government Information: How to Find It, How to Use It*.^[35]

INTERNATIONAL PUBLICATIONS AND ORGANIZATIONS

Patrons also seek out international government information, and the first place they typically look will be a search engine. This is a rational decision but may lead to frustrations. Most recent international government information is online (free or priced—and sometimes both at once) and legacy collections are rapidly being digitized. In this environment, one could argue the role of the library is marginal, but things are not that simple. The volume of international government information is immense, and much of it is embedded in the "deep Web" of databases that must be queried. Some international government information is distributed exclusively on priced electronic libraries or sold in print and/or online formats by commercial publishers. Other international organizations (IOs) distribute Machine Readable Cataloging (MARC) records for their publications, which enhances discovery for patrons unaware of the nature of their work. In an environment of "too much information," libraries still have a valuable role to play in providing access, curation, and preservation of this material.

IGOs and NGOs

If the concept of international governmental organizations (IGOs) is unfamiliar to some, the *Yearbook of International Organizations* is a good source to start. Edited by the Union of International Associations and published by Brill, the *Yearbook* is not just a directory of names and addresses. The online version contains searchable entries of over 66,000 IOs including both intergovernmental organizations (IGOs) and international nongovernmental organizations (INGOs) in over 300 countries and territories. Approximately 1200 new organizations are added

each year.^[36] The print *Yearbook* set of six volumes includes organizational descriptions with information broken down by subject, country, and region. A separate volume identifies organization publications and resources, and there are additional volumes for statistics and visualizations, memberships, and secretariats. Additional information is available at <http://www.uia.org/yearbook>.

IGOs are generally defined as 1) treaty-based, 2) made of three or more member states, and 3) having a secretariat for ongoing tasks. Statistics from the current *Yearbook of International Organizations Online* show that as of 2013/2014 there were 7710 IGOs.^[37] Definitions of nongovernmental organizations (NGOs) vary, but generally NGOs are 1) individual/nongovernmental actors and 2) voluntary associations. NGOs are often specialized in their goals, and work to make improvements in the fields of the Environment, Human Rights, Education, Women's Issues, Humanitarian Aid, or Economic Development. Think-tanks and independent research institutes are sometimes also included.

Examples of well-known NGOs include Médecins Sans Frontières, The International Red Cross, Partners in Health, Transparency International, and Oxfam. More widely recognized NGOs are often based in developed countries, but this is changing as NGOs in China and the Global South become better known: examples include the Grameen Bank, BRAC, and Friends of Nature (自然之友). Statistics from the current *Yearbook of International Organizations Online* show that as of 2013/2014 there were 58,588 NGOs.^[37]

Both IGOs and NGOs offer a wealth of statistical, historical, and administrative information that can help librarians serve their patrons' information needs. Libraries can develop and provide access to international information collections through a variety of avenues. Six IO collection development strategies and access models are discussed in this article. These include the following:

1. IGO depositories
2. IGO/NGO information on the Web
3. Digital MARC records
4. IGO publications offices
5. IGO priced databases
6. Third-party vendors that distribute IGO and NGO information IGO depository programs

IGO depositories

Historically, IGOs distributed documents and publications to a global network of depositories, chiefly based at national libraries and universities. With the widespread availability of free digital content, one could argue that IGO depository libraries have become irrelevant except as warehouses of historical print collections, destined for eventual digitization. We are indeed in the midst of a significant transformation. In 2010, the Asian Development Bank (ADB)

announced it would cease print distribution of depository materials except a handful of flagship publications. Tangible depository publications from the Organization for Cooperation and Security in Europe (OSCE) are now issued exclusively on an annual DVD. Document distribution from the European Union (EU) depository program has declined significantly, with some EU agencies no longer publishing anything in print. In 2012, the United Nations (UN) Depository Library System office in New York ceased distribution of print publications, although some material is still dispatched via its global network of offices. The UN Dag Hammarskjöld Library is developing a digital depository for UN documents, but at present no UN Sales Publications will be available for download on this platform. UN Depository Libraries will need to subscribe to a fee-based digital library constructed in partnership by the Organization for Economic Cooperation and Development to search for and download publications within a consolidated database environment.

Details about the current UN Depository program is available at <http://www.un.org/depts/dhl/deplib/index.html>

And information about EU depositories is at <http://www.euintheus.org/resources-learning/depository-libraries-in-the-us/>.

However, IGO depository libraries or the information professionals working in them are not relics of a bygone era. Effective government information retrieval is an advanced skill and librarians at these depositories possess a wealth of knowledge and historical collections one can tap into for assistance. Any librarian needing assistance with international information can contact these specialists, or use the Web guides created by them as reference sources.

Freely available IGO and NGO information on the Web

All IGOs and NGOs now provide substantial amounts of information on their Web sites, and some have taken the dramatic step of publishing virtually all of their unclassified documents online, free of charge. While there are certainly exceptions to this (see later text), the trend is unmistakable and linked to the open government, open access, and open data movements championed by libraries and civil society organizations.

IGOs, like the UN and the EU, and International Financial Organizations like the World Trade Organization (WTO) have published “documentation” (working documents and official records created by an organization in the course of conducting its business) online for years: examples include the United Nations Official Documents System (<http://documents.un.org/>), the World Bank’s Projects and Operations (<http://www.worldbank.org/projects>), and the WTO’s Documents Online (<https://docs.wto.org/>).

Other organizations such as the World Health Organization, which historically did not release any public documentation, now do so also (<http://apps.who.int/gb/bd/>). More IGOs are following suit. This movement allows access to IGO documentation scarcely imaginable only a few years ago as citizens now have digital access not just to publications produced and sold by IGOs, but also to information about their deliberative processes, budgets, decisions, and official records.

In addition, many IGOs now post previously priced “publications” (monographs and serials intended for use by the general public) freely online also. The World Bank, in a dramatic move in 2012, launched its “Open Access Policy,” which requires that “Bank research outputs and knowledge products be deposited into the World Bank institutional repository (the OKR), allowing any user in the world to read, download, save, copy, print, reuse and link to the full text of the work, free of charge.”^[38] This is among the most liberal publications policies of any IGO, but others are not so transparent: conditions of reuse, copyright, and access vary tremendously. The EU posts publications online at no charge, but has a copyright statement that only permits reuse of content published by the European Commission and the Publications Office.^[39] The UNESCO Open Access Policy is three pages long and quite complex.^[40] Other IGOs publish all, or virtually all, of their publications free online, but when in doubt check the policy and investigate the availability of digital content—you may be surprised.

Other IGOs publish only a limited amount of free content: examples include the Council of Europe, the UN Tourism Organization, the International Monetary Fund (IMF), and the OECD. Some IGOs sell their titles to commercial publishers who may publish the item in print or distribute them via e-book aggregators. The OECD licenses most publications via its subscription database, the OECD iLibrary, but there are free titles also. Publications from the Council of Europe (again, with exceptions) are priced, both in print and as PDFs. The IMF is making its priced online statistics databases free in 2015, but will still license an “eLibrary complete,” which will provide access to more than 14,000 IMF publications.

Furthermore, other IGOs offer both free and priced options for the essentially the same content. Some IGOs will sell a print publication on its bookstore, a priced digital copy on an electronic library, and a free digital version elsewhere its Web site. The World Bank eLibrary (<http://elibrary.worldbank.org/>) offers much of the same content found in the Open Knowledge Repository, but the eLibrary search is more robust and the historical content more extensive: it also includes MARC records. The subscription-based United Nations iLibrary (<http://www.un-ilibrary.org/>) also offers search and download features within a consolidated database environment—but in fact much of the same content can be found and downloaded elsewhere within the global network of UN agency web sites. But much of the same content should

also be free online via the wide network of UN agencies and offices around the world.

The resulting situation is thus very complex. Librarians, when considering which option is best suited for their clientele, should carefully consider whether print, free online, or priced online content best meets their needs: the various options all have advantages and disadvantages. Careful research should be conducted for each organization of interest as there is no consistency across the board, and policies can change rapidly.

And then, there is Open Data. Not long ago the UN, World Bank, IMF, and other IGOs sold most of their numeric data on subscription databases, prompting world renowned open data advocate Hans Rosling to diagnose them (during the H1N1 flu outbreak) with “DbHd” “Database Hugging Disorder.”^[41] Slowly but steadily IGOs have been curing themselves of this malaise. The UN was among the first, when it changed the name of its priced *UNSTATS Common Database* to *UNData* (data.un.org) and made it freely available online. Other previously priced data sets, including *FAOStat* from the Food and Agriculture Organization (FAO) and *World Development Indicators* from the World Bank, are now entirely free. The IMF is scheduled to make its subscription-based numeric databases, including *International Financial Statistics*, freely available in 2015. But other data sets, notably from the OECD and the International Telecommunication Union remain priced, as does the “premium access version” of *UN Comtrade*, the UN’s International Trade Database. What follows are some examples of freely available and commonly used IGO numeric databases:

United Nations—UNData: <http://data.un.org/>
 European Union—Eurostat: <http://epp.eurostat.ec.europa.eu/>
 World Bank Data: <http://data.worldbank.org/>
 International Labour Organization—ILOStat: <http://www.ilo.org/ilostat>

Digital MARC records

Even when international government information is online (free or priced), it may be buried so deep within a database that the information is virtually unfindable unless the patron knows in advance it exists. Some organizations have addressed this discoverability issue by assigning Digital Object Identifiers (DOIs) or Uniform Resource Identifiers (URIs) to publications, but not all. Here are two examples of IGO documents dealing with the Ebola Outbreak.

Economic Impact of the 2014 Ebola Epidemic: Short and Medium Term Estimates for West Africa. <http://hdl.handle.net/10986/20396>
Liberia Ebola Emergency Response—Update N.1 <http://www.fao.org/emergencies/resources/documents/resources-detail/en/c/243283/>

The first document has a URI that is easily cited: the second is more problematic. But whether a patron would have found either of these documents on search engine is debatable: many patrons would not have thought of the World Bank or the FAO when researching Ebola. To address this problem, libraries may wish to upload digital MARC records into their catalogs that some IGOs make available. With MARC records, a patron does not need to know in advance about the work of an international organization: they can find these documents in a keyword search in the catalog. Examples of IGOs that offer this service include the following. Some are free; others are priced via Electronic library subscriptions.

OECD iLibrary (subscription-based): <http://www.oecd-ilibrary.org/about/about>
 Asian Development Bank: <http://www.adb.org/publications/marcrecords>
 World Bank eLibrary (subscription-based): http://elibrary.worldbank.org/page/services_benefits
 EU Bookshop Publications Services for Librarians: <http://bookshop.europa.eu/en/publications-office-services-for-librarians-pbOA0114666/>

Another way patrons can search for IGO and NGO publications of interest is to use one of the Google Custom Search Engines that conduct searches across hundreds of IGO and NGO Web sites. For more information and links to these please, see next.

IGO publications offices

A number of large IOs have online bookstores for print publications. Furthermore, even smaller IOs will have their publications either online for free or available for order and purchase. A few of the more popular IGO bookstores include

EU Bookshop: <https://bookshop.europa.eu/en/home/>
 OECD Online Bookshop: <http://www.oecdbookshop.org/>
 United Nations Publications: <https://shop.un.org/>
 World Bank Publications: <https://publications.worldbank.org/>

The fact that many of these publications are free online has not stopped this business, and libraries may wish to consider print publications for clientele who prefer them, or for preservation and archival purposes.

IGO subscription databases

Another avenue of providing IO information to patrons is through IGO subscription databases. Even when much IGO content is free online, the benefit of acquiring these

is that the information is consolidated into one place, allowing patrons to perform detailed searches by country, topic, or time period. Most databases include MARC records and some include longer runs of historic material. Examples include

World Bank Elibrary: <http://elibrary.worldbank.org/>
 OECD iLibrary: <http://www.oecd-ilibrary.org/>
 IMF eLibrary/eLibrary Complete: <http://www.elibrary.imf.org/>
 UNWTO Elibrary: <http://www.e-unwto.org/home/main.mpx>

Third-party vendors for IO information

Many libraries work through third-party vendors to obtain international publications. This can be useful for placing standing orders for specific categories of publications or obtaining difficult to find or out-of-print material. Some leading vendors include

Renouf Press: <http://www.renoufbooks.com/>—"North America's leading distributor of governmental and international reports and documents."

Bernan Press: <http://www.bernand.com/>—"A leading distributor of essential publications from the United States government and intergovernmental organizations."

Readex United Nations Documents Collections: <http://www.readex.com/content/united-nations-documents>—Only comprehensive digital index to United Nations documents from the founding of the UN to present, as well as a collection of UN documents on microfiche. The avenues a library takes to build collections will depend on the library's goals, patron needs, finances, and staffing resources. Many libraries use several means to add International Organization information to their collections.

Professional Organizations and Online Research Guides

Any librarian or informational professional interested in international information should consider joining the Government Documents Roundtable (GODORT) of the American Library Association. GODORT's International Documents Task Force (IDTF) is a group of professionals who work with or specialize in this field. Their Web site is located at http://wikis.ala.org/godort/index.php/International_Documents and contains lists of current projects, research guides, and other valuable information. It also contains links to library research guides, some of which are listed next.

As a general note, many comprehensive government information guides have been "retired" as online search

has improved and governments have improved the usability of their own sites. What is increasingly done is librarians create research guides that explain the process of finding, understanding, and interpreting information for international organizations.

Finding IGOs

Northwestern University's International Government Organizations: <http://www.library.northwestern.edu/libraries-collections/evanston-campus/government-information/international-documents>.

Union of International Associations' Open Yearbook (free version of the priced yearbook): <http://www.uia.org/ybio/>.

IGO Custom Search—Google custom search engine for IGOs, sponsored by GODORT and maintained by James Jacobs at Stanford University: http://wikis.ala.org/godort/index.php/IGO_search.

Finding NGOs NGO Research Guide at Duke University: http://guides.library.duke.edu/ngo_guide.

Idealist—Online directory of NGOs searchable by region and area of activity: <http://www.idealists.org/>.

NGO Custom Search—Google custom search engine for NGOs sponsored by GODORT and maintained by James Jacobs at Stanford University: http://wikis.ala.org/godort/index.php/IGO_search/.

Finding foreign national governments

Northwestern University's alphabetical list of foreign national government Web sites: <http://www.library.northwestern.edu/govinfo/resource/internat/foreign.html>

Foreign Information by Country at the University of Colorado Boulder: <http://ucblibraries.colorado.edu/govpubs/for/foreigngovt.htm>

Detailed information about specific organizations

United Nations Dag Hammarskjöld Library Research Guides: <http://research.un.org/en>

European Union Research Guide: <http://www.law.georgetown.edu/library/research/guides/EuropeanUnion.cfm>

WTO & GATT Research: http://nyulaw.libguides.com/wto_gatt

CONCLUSION AND OUTLOOK

Given the rise of e-government, it is likely that future users will demand more online access to government information while tangible collections of materials will be few and far between. Requests for government

information are growing across all nations and at all levels of governments. In many ways, all government information is becoming local in that demand is based on how the release of the information impacts the local community. In order to meet future demands, librarians must build their documents collections (both physical and virtual) based upon the overall mission, goals, and audience of an individual library.

In 2012, the U.S. Government Printing Office (later the U.S. Government Publishing Office) began a strategic planning process to outline the future of the Federal Depository Library Program. A series of forecast questionnaires and action plans will eventually result in a new national plan for the program that will attempt to ensure permanent access to published federal information, no matter the medium in which it is issued. On a grander scale, national and local governments around the globe will continue to grapple with controlling the flow of information. In the digital era, ensuring the security of information that is not intended for public release has become as great a challenge as ensuring ongoing access to public information.

Greece: Archives

Nestor Bamidis

GSA-Archives of Macedonia, Thessaloniki, Greece

Abstract

This entry discusses the development of national and regional archives in Greece, focusing on the period from the early twentieth century to the present. College and university archives, private archives, and audiovisual archives are also discussed. Archival science is a new field in Greece. The Society of Greek Archivists was founded in 1990, and the first university level archival studies program was established in 1993 at Ionian University.

NATIONAL ARCHIVES AND SERVICES

The Greek national archive service is the “General State Archives” (Genika Archeia tou Kratous, GSA). It was established in 1914 by the Eleftherios Venizelos government and aimed at “the collection and supervision of all historical and public archives, including documents dated up to 50 years ago.”^[1] The foundation of the archive service was the result of the efforts of two exceptional men, the historian Spyridon Lamprou and the author and history researcher Giannis Vlachogiannis. The already existing Archives of the Ionian Islands, Crete, and Samos were incorporated into this service as well. Giannis Vlachogiannis, who donated his valuable collection to the Hellenic State, was the first director of the GSA. The next act was voted in 1939.^[2] The legislation in force today concerning archives consists of the following Acts: 1946/1991 “GSA and other provisions”^[3] and 2846/2000 “Archives of the Prime Minister, the Ministers, deputy ministers, and the General Secretariat of the Council of Ministers.”^[4] Access to public information is regulated by Act 1690/1999 (Article 5, “Access to documents”), in effect of article 5A of the Constitution, 2001^[5] and Acts 1599/1986, article 16, “Right of access to administrative documents,” and 1943/1991, article 6, “Publicity of administrative actions.”

The Constitution of Greece:

All persons have the right to information, as specified by law. Restrictions to this right may be imposed by law only insofar as they are absolutely necessary and justified for reasons of national security, of combating crime or of protecting rights and interests of third parties.

All persons have the right to participate in the Information Society. Facilitation of access to electronically transmitted information, as well as of the production, exchange and diffusion thereof, constitutes an obligation of the State, always in observance of the guarantees of articles 9, 9A and 19.

The protection of personal data is regulated by Act 1472/1997 on the Protection of Individuals with regard to

the Processing of Personal Data, enforcing article 9A of the Constitution, 2001:

All persons have the right to be protected from the collection, processing and use, especially by electronic means, of their personal data, as specified by law. The protection of personal data is ensured by an independent authority, which is constituted and operates as specified by law.

The GSA has been since then, with the exemption of a short period (1971–1985), fallen under the jurisdiction of the Ministry of National Education and Religious Affairs. The state archives service was reorganized in 1939 by an act in force until 1991, when it was substituted by Act 1946/1991.

The GSA operate according to the provisions of act 1946/1991 and constitute an autonomous, unified public service, under the auspices of the Ministry of Education and Religious Affairs. Issues concerning Archives are managed by the Direction of Libraries and General, with the administrative support of the Department of Historical Archives of the Ministry of Education and Religious Affairs.

The primary mission of the GSA, as described in article 9 of the above act, reads as follows:

- The supervision, preservation, collection, conservation, cataloging, micro photographing, arrangement, and indexing of the archival material of the country. Making all public and private records, documents, and manuscripts concerning the cultural heritage of the Greek nation and the administrative, economic, and social activities of the Hellenic State available to researchers for consultation;
- Location of public records of historical interest, their selection, acquisition, and transfer in the GSA, their preparation for consultation by the researchers and the creation of finding aids;
- Supervision of the special archives, which are founded and operate in public agencies;

- Publication of archival studies and catalogs;
- Cooperation with the church authorities, monastic institutions, and other religious authorities for the preservation of archival material;
- Cooperation with owners of private archives, which have historical interest;
- Enrichment of its collections by purchase or acceptance of donations of archival material by private owners and copies of archival material in the possession of foreign countries or organizations; and
- Participation in scientific research, in cooperation with other scientific authorities as well as in all kinds of exhibits, in Greece and abroad.

The Archival Service is divided into the Central and the Regional Services. The head of the Service is the “Director of the General State Archives.” The GSA of Greece are governed by a Board of nine members, whose duty is to decide, give expert opinion or advice on various matters concerning archives, based on proposals of the Director of the GSA.

The Central Service consists of the following departments: The General Index Department, the Contemporary Archives Department, the Organizing and Planning Department, the Department of Secretariat and Accounting, the Conservation and Reproduction Department, and the Reading Room and Library Department.

The regional services are divided into a) the Archives of the prefectures (nomoi) seated at the capitals of the prefectures, entitled and having the name “GSA—Archives of the Prefecture of . . .” and b) Archives operating in towns of the Prefectures and having the title “GSA—Local Archives of . . .” The responsibilities of the regional services are relevant to those of the Central service. Today, the network includes 62 services, covering the mainland and all the islands of Greece.

Archives in any kind or form, of all public agencies, of judicial authorities, local authorities, educational institutions, and notaries are collected and deposited in the GSA. The holdings of the GSA also include private archives, and their acquisition is considered to be of great importance. For that reason, an effort is made for the enrichment of the private archives collections by purchasing archival material and by seeking active collaboration with donors, holders, or owners of private archives of historical interest.

The GSA at the Prefecture level collect and keep the archives of the public and local authorities, judicial records, notaries, and educational records as well as private collections.

INDIVIDUAL STATE ARCHIVES

A special mention should be made of certain Archives having significant archival material. They include the following:

- *The Central Service*, where archives date back to the period of the Struggle for Independence (early nineteenth century) and the establishment of the Greek State are kept.
- *The Historical Archives of Macedonia*, where archives created by the Ottoman government and concerning certain areas of Macedonia (Thessalonicki, Veroia, Kilkis, Katerini, and Chalkidiki) are deposited. This includes the archives of the Religious Court (1694–1912), archives of administrative and judicial acts (1875–1912), and estate and tax registers.
- *The Historical Archives of Epirus* (Ioannina) which keep archives of the General Administration of Epirus (1912–1940).
- *The Archives of the Ionian Islands* (Corfu, Kefalonia, Ithaca, Zakynthos, Lefkada, Kythira, and Paksoi), which keep archives of their governments before their union with Greece. These include archives of the Venetian domination the “Serenissima Signoria” of St. Mark (1500–1789), of the Democratic French (1789–1799), of the Ionian Government (1799–1807), of the Imperial French (1807–1814), of the Cambell’s provisional government (1814–1817), and of the English Protectorate (1817–1864).
- *The Archives of the Prefecture of the Dodecanese*, where archives of the Italian administration, Ottoman manuscripts, archives of the Greek military administration, and of the General Administration of Dodecanese are deposited;
- *The Historical Archives of Crete* keeps archives of the Ottoman administration, as well as the official correspondence of the Cretan revolutions (1821–1835, 1866–1869, 1877–1878, 1895–1898 and 1905), archives of the Cretan State, of the German Occupation, during the Second World War, as well as private collections about important periods of Cretan history;
- *The Archives of Samos*, where collections (various documents—Ottoman, ecclesiastical, etc. of the eighteenth and nineteenth centuries) and archives of the Samian Hegemony (1834–1912) are saved.

STATE/PROVINCIAL AND LOCAL ARCHIVES

In Greece, all public Archives are incorporated in the GSA. As a result, archival agencies at the local authorities level (Provincial and Local Archives) are part of the State Archives. However, legislation concerning archives allows for the founding and operation of Archives by public sector agencies. Some of the most important are mentioned below:

- *Center for the History of Thessaloniki* The Center houses the municipal historical archive. Part of this archive is kept in the Center’s building and is gradually becoming accessible to scholars. The Center also

possesses a number of important private archival collections. It contains an important photographic collection, a map collection, and a collection of postcards printed in the beginning of the twentieth century.

- *Municipal Center for History and Documentation of Volos*.^[6] The Center possesses today a rich archive, consisting of the Volos Municipality archive (1883–1982), numerous private archives concerned directly or indirectly with the city and its greater area, archives of old industrial enterprises, as well as important material of building plans, maps, aerial photos, slides/transparencies, and photographs. In the context of electronic processing of the archive collections and the compilation of an index, the Municipal Center for Historical Research and Documentation, in cooperation with the *National Documentation Center*, proceeded with the electronic publication of the search tools for the archival collection.

COLLEGE AND UNIVERSITY ARCHIVES

Some of the oldest and most important universities in Greece have gathered archival material related to their domain or to their own activity. To name a few:

- *The Historical Archive of the National and Capodistrian University of Athens*^[7] was established in 1991 and since then has constituted an important research and administration unit of the University. From the beginning, the main goal was the gathering of archival material, scattered since the foundation of the University in 1837. Today, archives from that date up to 1970 are well organized, arranged, and described. Electronic finding aids are also available, as well as a growing number of digitized documents. The Historical Archive has created a solid infrastructure for the study of the history of university education and science. It also participates in research programs on Modern Greek and European history, in collaboration with universities and research centers all over Europe and contributes to the organization of archives and records management in other Universities, institutions, and business establishments.
- *The Aristotle University of Thessaloniki Historical Archives* Its educational, literary, social, and historic archival collections, concerning Macedonia (mainly from the beginning of the nineteenth century until 1950), are kept in different Departments of the University. The holdings of the historical archives include documentary records from the Teachers College of Thessaloniki (1933–1990), elementary and secondary private and public schools, educational authorities, hospitals, parishes, and monasteries.

OTHER ARCHIVES

There are also organizations maintaining important collections of specific interest, due to their nature or acquisition policy. Some representative examples include the following:

- *The National Bank of Greece Historical Archives (NBG)*^[8] were set up for the preservation and display of archival material of the National Bank of Greece, deemed to be of historical importance. The NBG has demonstrated particular concern for its archival material since its early days. As a consequence, NBG possesses a comprehensive historical archive whose time span coincides practically with the history of the Modern Greek state. The material held in the NBG Historical Archives covers the Bank's history from 1841 to 1966, while it also contains originals or copies of various archives of other institutions or individuals entrusted to its safekeeping.
- The *Hellenic Literary and Historical Archive*^[9] keeps an important collection of archival material (nineteenth and twentieth centuries), of historical, literary, social, economic, and artistic interest.
- The document collection of the *Foreign Ministry's Diplomatic and Historical Archive*^[10] encompasses the period from the beginning of the Greek national liberation struggle in 1821 to the present day. The Service of Diplomatic & Historical Archives of the Hellenic Ministry of Foreign Affairs (M.F.A.) is responsible for safe-keeping, preserving, classifying, and utilizing the written, audiovisual and electronic archives of the Ministry, and managing the Library and the Film Archive of the M.F.A.

AUDIOVISUAL ARCHIVES

In recent years, special care has been taken in Greece for audiovisual archives, which have been preserved in public agencies.

- The *Secretariat General of Communication and Information*^[11] maintains an important film archive (about 2100 titles), documenting important aspects of the political, economic, social and cultural life of Greece from 1908 to 1996. The material is divided into three categories: "Contemporary," "Chronicles," and "Documentary." A project of digitalization is currently aiming at facilitating the effective management and utilization of the film archive. According to Law 3444/2006, the film archive will be turned over to the National Audiovisual Archive.
- The task of the *Hellenic Audiovisual Institute Archive*^[12] is the conservation and preservation of audiovisual and

born-digital material, for wide access by any interested party. The Archive manages audiovisual and born-digital material with informational-news, historical-political and, in general, social-cultural content, related to the heritage of the Hellenic State and Hellenism as a whole.

- The *Archive Museum of ERT* (Hellenic Broadcasting Corporation)^[13] was established in 1990. It comprises the departments of the Museum, the Picture Archive, and the Audiovisual Archive. ERT's holdings of more than 15,000 reels of film, 300,000 negatives of pictures and photographic archives, are the most important ones of their sort in Greece. Since 1996, it has been operating as a maintenance and restoration workshop for films, while in 1999 it started operating as a restoration workshop for videotapes—the only one of its kind in Greece—as well as a workshop for the maintenance of photographic material.

The archival landscape in Greece could not be complete without mentioning the following institutions:

- Archive of Cinematograph and Archive of Documentaries of the Ministry of Foreign Affairs, http://www.mfa.gr/greek/the_ministry/history_archive/index.htm
- National Bank of Greece Cultural Foundation—Historical and Paleographical Archive, <http://www.miet.gr/web/en/archive/>
- Archives of Contemporary Social History, <http://www.askiweb.gr>
- Historical Archives of the Benaki Museum, <http://www.benaki.gr>
- Historical Archives of the Agricultural University of Athens, <http://www.aua.gr/gr/arxeio/>
- The American School of Classical Studies at Athens, <http://www.ascsa.edu.gr/archives/Gennadius/Catalog1.htm>
- The Konstantinos G. Karamanlis Foundation Historical Archive, <http://www.Karamanlis-foundation.gr/gr/drastiriotites/arxeio.html>
- Association for the salvage of Historical Archives 1940–1974 <http://www.edia.gr/>
- The Konstantinos K. Mitsotakis Foundation, http://www.ikm.gr/archive_purpose.cfm
- Army History Directorate, http://www.army.gr/html/GR_Army/dieuthinseis/DIS/index.html

DIGITAL ARCHIVAL COLLECTIONS AND ELECTRONIC FINDING AIDS

Most of the repositories mentioned above have digitized part of their collections and provide electronic finding aids, accessible over the Internet. During the last 5 years, a large number of digitization projects, funded by the EU

Information Society Operational Programme, have been launched and continue to be carried out.

ARCHIVAL STUDIES

Archival science is a relatively new field in Greece. Employment positions are available in the state archives (provided by law), while new prospects are being developed in the private (banks and corporations) and public (Local Administration, Police, Universities, and Research Centres) sectors.

A Department of Archival and Library Sciences was established at the Ionian University in 1993.^[14] It is a 4-year course of study leading to a Bachelor's Degree. Graduates may work as archivists in the GSA or in the archival institutions of the public or private sector, mentioned above. The Departments of Library Studies and Information Systems of the Technological Educational Institutions of Athens and Thessaloniki provide basic courses in Archival science (in two of the eight semesters). Graduates may take positions as assistant archivists in GSA and other archival institutions, or record managers in public and private organisations. Continuing education programs are available through seminars and workshops organized by the GSA, as well as the Society of Greek Archivists.

PROFESSIONAL ASSOCIATIONS

The Society of Greek Archivists was established in 1990.^[15] Society of Greek Archivists, the sole professional association of archivists in Greece, currently has more than 200 members, and includes archivists, historians, and researchers. Some of its main constitutional functions are attracting the attention of citizens and decision makers about the salvage and preservation of archives, promoting the national archival heritage, providing consultancy and expertise concerning the management of archives to various organizations, and promoting the archival training and education of the archives and record management professionals.

One of the main concerns of archival professionals is the management of electronic records as archival documents. Existing legislation is not adequate on this issue, while the implementation of the e-government project raises an important number of problems that should be resolved as soon as possible. This issue holds back the efforts of archivists concerning long-term preservation of the documents in their original form. Microfilming and digitization are starting to be widely used for improved access of archival information. On the other hand, there are institutions focused on managing special archival mediums, e.g., audiovisual *registrations*, maps, and plans. The GSA are promoting the standardization of best practices for the preservation of traditional and electronic documents.

Greece: Libraries

Anestis Sitas

Aristotle University of Thessaloniki, Thessaloniki, Greece

Mersini Moreleli-Cacouris

Department of Library Science and Information Systems, Technological Educational Institute (TEI) of Thessaloniki, Sindos, Greece

Abstract

This entry provides an overview of the development of different types of libraries in Greece. Although the authors make reference to what is known of similar cultural institutions in ancient Greece, the focus is on modern period from the Greek Enlightenment and the establishment of the modern state in the early nineteenth century to the present. Special attention is given to recent trends, challenges, and accomplishments.

INTRODUCTION

Greece, a peninsular country, plus an archipelago of many islands, is situated on the south-eastern edge of Europe. It contains an area of 131,957 km² and has a population of 10,964,020 (2001 census).^[1] Greece was declared independent in 1830 and has been a parliamentary republic since 1974. It has been a member of the European Union since 1981. The 2007 GDP amounts to 209,268 billion €, and the per capita annual income is 22,700 € (estimated figure in 2006) (Fig. 1).

LIBRARIES

History

The first indications of libraries in the ancient Greek world can be found in the Minoan and Mycenaean periods. The Library of Peisistratos (about 560 B.C.) is considered to be the first public library in Athens. The most famous library, however, was the Library of Alexandria, founded by Ptolemy II Philadelphus (309–246 B.C.). During the Byzantine Empire, the first “imperial” library was set up in Constantinople in the fourth century. Nevertheless, the kind of libraries that flourished at the time were monastery libraries (Mount Athos, Meteora, Patmos).

After the Fall of Constantinople to the Turks (A.D. 1453), some libraries continued to operate, while others ceased to exist. During the Modern Greek Enlightenment (late eighteenth to early nineteenth centuries), many schools were established, most of which had a library available to serve the needs of the curriculum. That period is considered the starting point for the modern era of libraries. The Library of Zagora, on Mt. Pelion, one of the most significant libraries in those days, opened its doors in 1762. Since 1955, it has

been known as the Public Library of Zagora. Another library opened at that time was the Library of the Dimitsana School, in the Peloponnese, which began to operate in 1764. Its present name is Public Library of Dimitsana. Finally, in 1828, the Zosimaia School, in Ioannina (Epirus), set up its library, which has borne the name Zosimaia Central Public Library of Ioannina’ since 1987.

Contemporary Libraries

Recently, as many as 1145 libraries were identified in a 1998 survey that aimed to record all libraries. Of all those libraries recorded, 61.4% were public libraries, 13.9% academic libraries, 2.9% school libraries, and 21.8% special libraries.^[2]

As far as book production is concerned, 730 publishers released 9209 new titles in 2006.^[3] A survey on reading behavior indicates that 43.8% of Greek citizens do not read at all, 19% read only “practical” books, 0.9% only professional books, and 2.4% read both practical and professional books. On an annual basis, 25.4% read a few books (one to nine) as opposed to 8.6% that read several books (over nine). When stating the way of obtaining their books, 70.8% indicate that they buy them themselves, 17.9% borrow them from their acquaintances, 4.7% borrow them from libraries, and 3.9% receive them as gifts.^[4] 28.9% of the Greek population aged 16–74 have Internet access.^[5]

For years, Greek libraries had been underdeveloped and provided poor services. There had never been a national plan for library and information development, and the involvement of various ministries, state, and local agencies in government created many problems in planning and coordinating services. The fact that the majority of Greek libraries belonged to the public sector, with limited funding available, made any efforts for improvement even harder. This has changed radically. Funding of libraries has

Fig. 1 Map of Greece.

Source: Modified from CIA *The World Factbook*.^[10]

undergone a positive change: more state funds are now made available and European Union funds have flowed into the country. Information technology has become a part of library operations and plays an important and dominant role in the dissemination of information. Users, introduced to the wealth of electronic sources, have become more demanding. The range, kind, and modes of services which are provided now reflect active organizations, and do not resemble the warehouse-type institutions of the past.^[6]

National Library of Greece (NLG)

After the liberation of Greece, the National Library of Greece (NLG) began to operate in Aigina, which was then the capital of Greece. It was established under the initial name of Public Library, by decree in 1832. In 1834, it was transferred to Athens, which had become the new capital of the Greek State. In 1842, it was incorporated into the library of the University of Athens, established in 1837 and in 1866, the above collections merged into a single library under the formal Greek title “*Ethniki Vivliothiki tis Ellados*” (The NLG).

Since 1903, it has been housed in a building that was erected with funding by the Vallianos brothers, merchants, ship owners, and bankers, who, in the nineteenth century had businesses in Russia, Marseille, Constantinople, and London. It was designed by the Danish architect Theophil Hansen and built under the supervision of Ernst Ziller, a prominent German architect, whose work constitutes a milestone in contemporary Greek architecture. On June

11, 2007, a memorandum of understanding was signed between the Greek State and the Stavros Niarchos Foundation, for the construction of a new building. The project is expected to be completed in 2013 (Fig. 2).

The NLG is under the authority of the Greek Ministry of National Education and its institutional framework is prescribed by Law 3149 (FEK A, 141/10–06–2003). Its collections include approximately five million documents, and it is the main legal depository library in Greece. It publishes the *National Bibliography* and it operates as the national center for the assignment of ISBN, ISSN, and ISMN numbering. The Library was granted the authority to transfer *Library of Congress Subject Headings* into a Greek database, translate them into Greek, and adopt them to the Greek context. Various bibliographic tools, such as the *Catalog of Greek Subject Headings* and a translation of IFLA’s *UNIMARC Manual* into Greek, have been published. Access to the library’s OPAC (Online Public Access Catalog) is now possible, enabling librarians to check their collections, locate and verify items and copy bibliographic data.

Parliament Library

The Greek Parliament Library (*Vivliothiki tis Voulis*) was founded in 1844. It is housed in three different buildings in Athens. The “Main Library” of the Parliament Building houses collections of social sciences, rare books dating from 1471 to 1850, and maps and engravings, as well as documents pertaining to modern Greek history. The “Benakeios Library” houses collections of humanities and sciences. It also contains the personal libraries of prominent Greek politicians and scholars. The “Old Tobacco Factory” was converted into a library and houses the Microphotography and Preservation Departments as well as the largest part of the collection of Greek newspapers and periodicals. Mainly for preservation reasons, the Library began in 1984 to microfilm its serial collections; the outcome was 14,500 microforms. Following this

Fig. 2 National Library of Greece.

project, the Library is digitizing its rare books and works of its art collections. Along with the National Library, the Parliament Library is one of the mandatory legal deposit agencies.

Public Libraries

When discussing Greek public libraries some clarifications need to be made. In the Greek context there are two kinds of public libraries, depending on the supervising and regulating authorities; the “dimosies” (public) and the “dimotikes” (municipal).

Public libraries operate within a common institutional framework and are under the authority of and funded directly by the Greek Ministry of National Education. Their operation is prescribed by Law 3149. Their by-laws have been established by Ministerial Decision 83064/IZ (FEK B, 1173/20–8–2003). There are 45 such libraries spread throughout the country.

On the other hand, municipal libraries belong to the respective municipalities that provide their funds. This results in the lack of uniform regulations concerning the operation of these libraries and, as a consequence, there is considerable diversity in the way municipal libraries are organized and funded. A network of mobile libraries has been in operation since the early 1960s, to serve small communities and schools in remote areas. Of those, 38 operate as part of public libraries, two operate under the Ministry of Macedonia-Thrace, and another 11 libraries operate, since 1992, under the Union of Local Authorities, offering services to an equal number of prefectures.

In 2003, within the framework of the European Union’s Information Society Operational Program, Public Information Centers were set up in 45 public and 30 municipal libraries; funding for networking and computing was included. Also electronic equipment to facilitate people with special needs to access the centers’ electronic sources, was acquired. A network of mobile libraries has been in operation since the early 1960s, to serve small communities and schools in remote areas. Of those, 38 operate as part of public libraries, 2 operate under the Ministry of Macedonia-Thrace and another 11 libraries operate, since 1992, under the Union of Local Authorities, offering services to an equal number of prefectures.

Central Public Library of Veroia, Macedonia: Founded in 1952. Since 1976, it has operated as a public library. Under the direction of Ioannis Trochopoulos, it has become a leader in the field, implementing new technologies, cooperating with libraries in other countries, and participating in European projects. In addition to its innovative services, it offers free Web page hosting to local cultural associations and educational bodies and maintains the portal of Greek public libraries (infolibraries.gr) (Fig. 3).

Central Public Library of Sparta, the Peloponnese: Founded in 1972. Since 1989, it has operated in a new

Fig. 3 Public Library of Veroia.

building. It is one of the first public libraries to provide equipment for people with special needs. Under the leadership of E. Tzinieri-Tzanetakou, and in cooperation with other institutions, it developed and published library standards and building specifications for Greek public and school libraries.

Municipal Library of Thessaloniki (Founded in 1932) Originally under the leadership of G.M. Cacouris, it is one of the few municipal library systems, that since 1984 has been organized in a modern way, based on international standards and staffed by professional librarians. It comprises the Central Library, which has been housed in a new building since 2000, and a network of 15 branch libraries, including very active children’s libraries. The total of its collections amounts to 220,000 books. It has the most comprehensive collection of newspapers and periodicals in Northern Greece (Fig. 4).

The Vafopouleio Cultural Center, also under the authority of the Municipality of Thessaloniki, was founded in 1983 with funds provided by the eminent poet George Vafopoulos and his wife Soula Gerakopoulou. The Center, which includes Libraries, an Art Gallery, and a Theater has had a positive impact on the cultural life of Thessaloniki.

School Libraries

While the establishment of the first school libraries dates back to 1835, school libraries have yet to be valued by the Greek educational system. Libraries in a number of private secondary schools (Athens College, Anatolia College of Thessaloniki, and Pierce College) were until recently the only examples of well organized and functioning school libraries. The centralized Greek educational system, the outdated learning styles, the heavy schedules of students, the absence of professional librarians in schools, and the lack of appropriate space are some of the reasons for this pattern. Also, the prevalence of the one textbook

Fig. 4 Municipal Library of Thessaloniki.

for every subject, the same in all primary and secondary schools throughout the country, is another reason for the low priority libraries have in the educational system.

The situation of school libraries is changing. The 499 libraries, founded in secondary education schools in 1999, were the first properly organized state school libraries. They were provided for the first time with an institutional framework by a special decision of the Greek Ministry of National Education (19/11/2003, acc. no. 128800/G7/Es. F.11/1240). The development of EDUNet, a national network for primary and secondary education, connects school libraries with the international information world. ABEKT has been used for the automation of all library functions, ensuring standardization. The establishment of another 266 libraries in secondary education schools as well as the pilot establishment of 25 libraries in primary education schools are well under way.

Academic Libraries

In Greece, public higher education is comprised of 22 universities and 15 Technological Educational Institutions (TEIs). Until, the late 1970s the educational system did not require the use of libraries, especially for undergraduate studies. Students relied mainly on professors' lecture

notes or on a single textbook. This, along with the fact that the Greek educational system in the nineteenth century was influenced by the German educational model, resulted in the creation of small departmental collections in every institution. Laws 1268 (art. 7, par. 7, FEK A, 87/16–07–1982) and 1404 (art. 49, par. 5, FEK A, 173/24–11–1983), and Law 3404 (art. 16, FEK A, 260/17–10–2005), which provides for the existence of only main libraries and libraries at the faculty level, have been adopted to rectify this fragmentation.

The necessity to converge on and participate in the integrated European educational environment of higher education, and generous funding from the European Union within the Community Framework of Support (from 1996 onwards) were critical for academic library development. Libraries were staffed with professional librarians, the necessary technological infrastructure was established, their collections were developed, and electronic services were organized and offered. National policies in certain areas were developed and common decisions were taken.

National and Capodistrian University of Athens: Founded in 1837, it was the first university in the Balkans and the Eastern Mediterranean. Due to the fact that the university buildings were scattered over a large area, 47 independent branch libraries were created, which, following a decision of the Rectorial Council in 1998, were united to form 12 Central Libraries. Although they administratively belong to and are supervised by the respective academic departments, they are "managed by" the Library Management Center of the University of Athens.

Aristotle University of Thessaloniki: Founded in 1925, it is the largest academic institution in Greece. Although a large number of branch libraries were originally created, currently the libraries constitute a single system with one catalog and common by-laws. However, they are funded and economically managed independently. Apart from the main library (in operation since 1974), the system comprises of four subject and 40 branch libraries. It has been a pioneer in automating its collections, acquiring electronic sources, digitizing its material, and providing electronic services to its users (Fig. 5).

University of Macedonia of Economics and Social Sciences: This is a Thessaloniki-based university that was founded in 1948 and began its operation in 1957. Its library was established in 1962, and since 1993, under the leadership of its director Anna Fragkou, it has been reorganized, provides innovative services, and participates in many European projects. It is also the leader among academic libraries in providing services to students with special needs and organizing seminars and workshops to train librarians in this area.

University of Crete: It was founded in 1973 but began to operate in 1977. Its library includes the main library in Rethymno and three branches in Irakleio. Under the guidance of Michalis Tzekakis, it was the first large academic library in Greece to be organized as a single administrative

Fig. 5 Aristotle University of Thessaloniki Library.

unit, and served as a model for the organization and management of other academic libraries. Michalis Tzekakis is also to be noted for his pioneering efforts for the automation of academic libraries and their cooperation on the national level. It was one of the very first libraries to have connections and cooperate with foreign libraries and has carried out many advanced and innovative projects; on the national level. The most serious attempt to create software for the automation of library procedures was PTOLEMEOS, which was in operation in various libraries from 1985 to 2004 (Fig. 6).

University of Patras: Established in 1964, the library started to operate in 1966 to serve the needs of a new University. Committed to quality, change, and improvement, it was the first Greek library in 1988, under the leadership of Catherine Synellis, to subscribe to electronic databases. It is currently involved in digitization projects and quality assessment efforts.

Special Libraries

In the 1998 library survey, 341 special libraries were recorded. They include libraries operating in organizations of the public or private sector (35.2%), research institutions (17.9%), hospitals (19.4%), cultural institutions (12.9%), banks (4.4%), churches (5.3%), and prisons (5%).^[2]

The Gennadius Library: It was created in 1922 when the personal collection of Ioannes Gennadios, a diplomat, was donated to the American School of Classical Studies at Athens. The Carnegie Foundation undertook to erect the building on land provided by the Greek State. It has the personal collections of Lord Byron and the scholar A. Korais as well as 42 archival collections (including the archives of Ali Pasha, the amateur archaeologist Heinrich Schliemann, the composer Dimitris Mitropoulos, and two Nobel prize winners—G. Seferis and O. Elytis, etc.).

Fig. 6 University of Crete Library.

Benaki Museum: Its library was established in 1931. It is the largest museum library in Greece. Since 1991, it has included as a branch the library of the N. Chatzikyriakos-Gkikas Gallery, holding the personal collection of the famous painter.

Music Library of Greece “Lilian Voudouri”: Although there are two more music libraries operating in Greece (University of Thessaloniki and Ionian University in Corfu), this was the first Greek library to fully deserve its name. It was founded in 1997 by the Friends of Music Society. It houses books, sheets of music, and sound recordings, as well as the archives of composers, such as Mikis Theodorakis, etc.

Other special libraries worthy of mention are those of the Benaki Phytopathological Institute, the Center for Planning and Economic Research (KEPE) and the Technical Chamber of Greece (TEE).

DIGITAL LIBRARIES AND INSTITUTIONAL REPOSITORIES

Following the trend for the digitization of Europe’s cultural heritage and the provision of a common access point, Greek cultural institutions have been active in this area. There are 75 digital collections to date. Of these, 30 are full-text collections, 15 are book databases, five combine the types above, 19 are defined as institutional repositories, and the remaining six are collections of online periodical articles. As regards the software used, 32 are open-source applications and 30 collections use commercial applications.^[7] Besides the above projects, one of the largest Greek digitization projects is currently under way; public libraries and the NLG, will digitize their rare book collections, estimated to amount to 15 million pages.

Anemi: Created in 2006 by the Library of the University of Crete. It contains digitized material on Modern Greek culture. Digital Library, the first institutional repository of

a Greek institution, has been in operation at the same university since 1997.

e-fimeris: The National Library Newspapers Digitization Project has the full text of five newspapers of the period 1893–1983.

Psifiothiki: It is being implemented by Aristotle University of Thessaloniki, starting in 2003. It includes newspaper and magazine articles on Greek philology and theater. The university's institutional repository is being implemented using the same database.

Digital Collections and Institutional Repository at NTUA (National Technical University of Athens): The digital collection began in 2005 and includes 300 books and periodical titles. The repository began to operate in 2007.

National Documentation Center, Digital Library: Creator and owner of 22 mainly bibliographic databases, such as Argos and the full-text database of Hellenic Doctoral Theses.

NETWORKS, CONSORTIA, AND UNION CATALOGS

Hellenic Academic Libraries (HEAL)-Link: The Association of Greek Academic Libraries was established during this trend toward modernization. Heal Link (Syndesmos Ellinikon Akadimaikon Vivliothikon), began to operate in 1997 and took its final legal form under Article 17 of Law 3404 (FEK A, 260/17–1–2005). Its members are 37 academic institutions, 17 research institutions, the Academy of Athens, the National Library, the Parliament Library, and the University of Cyprus. The Association is a significant innovation on the library scene, since this is the first time there is planning and action at a central level. Today all academic and research institutions have access to digital material and services, a central union catalog was created, and an interlibrary loan network started to operate. The number of e-journals and e-books that the libraries have access to through the consortium is quite impressive, when compared to the number of journals academic libraries had access to in the print world. Access to the full text of about 14,000 journals is provided, and while it started off with 202,500 downloads, in 2006 it reached about 4.5 million. Claudine Xenidou-Dervou, Librarian at Aristotle University of Thessaloniki, is recognized for her significant effort in the creation and maintenance of Heal-Link.

Zephyr: Virtual Union Catalogue of Greek Academic Libraries. Created in 2003 by the Technologies and Information Service of the University of Crete Library, it supports MARC21 and UNIMARC formats and its design is based on the Z39.50 protocol. It includes all bibliographic records of Greek academic libraries in real time.

Union Catalog of Greek Academic Libraries: It includes the catalogs of Greek academic libraries. Its participants are the Academy of Athens, the National Library,

the Pedagogical Institute, the University of Cyprus, and the Open University of Cyprus. Works on its creation began in 1997, while it first operated in 2005. It is a main (natural) slave type catalog. It uses the UNIMARC format.

Greek Public Libraries Union Catalog: It includes the collections of public libraries and began to operate in 1999. The Central Public Library of Levadeia undertook its creation, with support from the Greek Ministry of National Education and the EKT. It is an integrated catalog that has a master record for each document and supports the UNIMARC format. The records of 10 libraries have been included to date.

Union List of Serials: Since 1984, the EAT has developed and managed the national union catalog of scholarly journals held in Greek libraries, through which online ordering for interlibrary loan can be done. Some 250 Greek libraries of all types participate in the project and make their print journal collections nationally available.

Openarchives.gr: A search engine, based on open-source software, has been in operation since 2006. It conducts simultaneous searches of Greek digital libraries and institutional repositories.

OTHER RELEVANT BODIES

National Documentation Center (EKT): Pressure exercised by the Greek scientific community resulted in 1980 in the establishment of the National Documentation Center. The Center, supervised by the Ministry of Development General Secretariat for Research and Technology, is the national organization for the development of an information system for science and technology.

The Greek doctoral dissertations database, and 20 more bibliographic databases, along with union catalogs of various types of libraries, have been developed by the Center. It has also produced an integrated library automation system, ABEKT, which has solved automation problems in many small libraries, which otherwise could not have afforded to purchase a commercially available system.

Organization of Juvenile and Adolescent Libraries (O.P.E.B.): Founded by the late Anne Gruner Schlumberger, a librarian originally from France, who wished to offer opportunities for culture and education to children coming from rural or underprivileged areas. Originally supervised and coordinated by the Ministry of Agriculture, in conjunction with local agricultural Cooperatives, it has been, since 1993, under the supervision of the Greek Ministry of National Education (Law 2174/1993). Today there is a network of 29 O.P.E.B. supported libraries throughout Greece, including three libraries in prisons.

National Book Center of Greece (E.K.E.BI): This independent legal entity was established in 1994 by the Ministry of Culture. Its goal is to formulate a national policy on books. Its main objective is to support and organize the book trade, with parallel activities focusing on readers and

books. "The modernization, support, and animation of libraries" are also included among its interests.

The Book Monitoring Unit (PAB): It was established in 1997 under the aegis of the National Book Center and is responsible for statistics and measurements about book production. In 1998, it developed the electronic book database BIBLIONET which contains Greek books in print.

Total Quality Management Unit of Greek Academic Libraries (MOPAB): It has been in operation since 1999, under the responsibility of George Zachos, director of the University of Ioannina Library. Its main objectives are to collect, process, analyze, and present data on Greek academic libraries, and to develop assessment indicators concerning academic libraries.

Union of Hellenic Librarians and Information Scientists (E.E.B.E.P.): The professional association of Greek librarians was founded in 1968, originally under the name Union of Greek Librarians. It was renamed in 2004 to encompass the new developments in the field. G.M. Cacouris was the first elected president. Its membership is around 2000. Regional divisions exist in the Peloponnese, Crete, Thessaly, and Northern Greece.

Association of Archivists and Librarians in Greece (E.A.B.E.): Founded in 2000, it is the professional body of graduates of University departments of archives and library sciences.

LIBRARY AND INFORMATION SCIENCE STUDIES

The first efforts to provide formal library education programs were made in 1957 through training seminars. On the invitation of the Greek State, UNESCO commissioned Leon Carnovsky (in 1960), professor at the University of Chicago, and Preben Kierkegaard (in 1962), director of the Danish Library School, to study the situation and make appropriate suggestions. They both proposed the establishment of a library science school at the university level. A 1-year vocational school was set up by the YWCA in Athens in 1961 and operated until 1976.^[8] G.M. Cacouris, as its director, and Maria Alexandraki, as member of its faculty, inspired, trained, and created employment opportunities for a large number of graduates. G.M. Cacouris also contributed to the establishment of library science departments at TEI, the new institutions founded in the early 1970s, in order to foster new emerging professions and applied disciplines.

In 1977, the Department of Library Science was set up at the TEI of Athens. Its name was changed to Department of Library Science and Information Systems in 2003, to reflect the new developments in the field. Alkmini Skandali and V. Moniarou, were among the first members of its faculty and worked for the development of a modern curriculum. Over 4000 students have graduated from the department to date. A second department was founded in 1981 at the TEI of Thessaloniki. Under the guidance of professors G.M. Cacouris and M. Moreleli-Cacouris, the

first library and information science collection in Greece was organized, exchange programs with schools in Europe and the United States were developed, and courses on information technology started to be taught. Over 2500 students have graduated from the department to date.^[9]

In 1993 the Department of Archives and Library Sciences at the Ionian University, Corfu was founded. George Bokos, contributed to the development of its curriculum, and soon the department started offering doctoral degrees; also since 2003, course-based master's programs have been organized, in conjunction with the TEI of Athens department.

PUBLISHING ACTIVITIES AND CONFERENCES

The publication of *Cataloguing Rules* (1969, 1974) and *Librarian's Dictionary* (1974) by G.M. Cacouris, as well as the *Bibliography of Greek Library Science* by K. Delopoulos (1974) were the first efforts to publish professional material in Greek.

The E.E.B.E.P. published (and continues to publish) the first library periodical, *Libraries and Information (Vivliothikes kai Pliroforisi)*, Issue 1 (June 1984). In addition, the E.E.B.E.P. has published handbooks and organized seven Panhellenic conferences (the last one in 1993). The Department of Archives and Library Sciences of the Ionian University has been publishing a yearbook *Document (Tekmirion)*, since 1998. Also, two short-lived titles *Modern Library and Information Services (Sygchroni Vivliothiki kai Ypiresies Pliroforisis)*, Issues 1 (March 2000) to 21 (August 2003) and *School Library (Vivliothiki sto Scholeio)*, Issues 1–3 (2001) were published by private publishers.

Libraries have started to implement Web 2.0 applications in order to communicate with their users. The EKT publishes the electronic newsletter *Public Libraries... on the Move (Oi Dimosies Vivliothikes ... kinountai)* (Issue 1/June 2004), and the Goethe Institute brings out the online magazine *Synergasia*, Issue 1 (April 2006).

The EKT also published the Greek translation of the 13th abridged edition of the DDC in 2001. Since 2002, it has developed and made available the first bilingual (Greek and English) *Thesaurus of Greek Terms of General Content*. AACR2 was published by TEI of Thessaloniki in 1996.

The annual conference of Greek academic libraries is an important event for the library community. It was first organized in 1992, and the library of a different institution organizes it every year.

CONCLUSION

With the establishment of library science departments and the provision of European Union funds from 1996 onwards, a new era has begun for Greek libraries. Libraries have managed to overcome the adversity of many decades,

creating a modern environment that meets the needs of the information society. New buildings have been erected, older buildings have been renovated and up-to-date equipment has been acquired. The appointment of professional librarians has been a significant factor contributing to success. Greek libraries, funded by European Union Programs, have started the digitization of conventional material and the management of born-digital material, and the provision of innovative services. They have learned how to cooperate, conduct research projects, and actively claim their right to participate in the new globalized information environment.

Greece: Museums

Maria Economou

Department of Communication and Cultural Technology, University of the Aegean, Mytilini, Greece

Abstract

The entry provides some general statistics about the number of museums and their visitors in Greece. It then examines the development of the idea of the museum from antiquity to modern times, focusing mainly in the nineteenth century, when the modern Greek state was founded. The first museums in Greece were associated from their beginnings with the strengthening of national identity and its links with ancient Greece, while they had a public mission and a strong educational character. In modern times the Greek museum scene shows an increasing interest in current museological concerns and practices. The entry covers in greater detail the National Archaeological Museum, the Byzantine and Christian Museum, the National Gallery-Museum of Alexandros Soutsos, and the Benaki Museum.

INTRODUCTION

There are over 280 museums in Greece that operate under the supervision and the administrative control of the Ministry of Culture (founded in 1971). The majority of these are archeological (165). They are legal entities governed by public law, but the Ministry also supervises 105 museums which are legal entities governed by private law. Apart from these, there are also a number of private, local authority, university, church, and independent museums, but there is not a reliable, comprehensive list of these, as they do not belong to the list of museums supervised by the Ministry of Culture.

According to the 2006 National Greek Statistical Service survey, about 2,800,000 people (Greeks and non-Greeks) visited the state museums (more than a third of whom were admitted free of charge).^[1] A 2007 Eurostat survey on European Cultural Values reported that only 25% of Greeks declared that they had visited a museum or gallery within the last 12 months (2006–2007) (average in the European Community: 41%), while a higher percentage, 33% had visited a historical monument (EC average: 54%).^[2] The Acropolis Museum was by far the most visited (annual average of over 1 million visitors between 1998 and 2005, while the rest had less than 400,000 visitors annually, on average). The same survey reported that 28% of Greeks use the Internet for visiting museum or library Web sites.^[3] According to another Eurostat survey, in Greece 2.1% (4382) of people in employment worked in the cultural sector in 2005, compared with 2.4% (4.9 million) in the remaining 27 countries of the European Union.^[4]

FROM ANCIENT TO MODERN TIMES

For ancient Greeks, “mouseio” was the sacred precinct of the Muses, the space dedicated to the protectresses of the

arts. During the Hellenistic period, the term referred by association to a research center and congregating point for the scholars of the time and was usually associated with a large library, like the one in Alexandria.

During the Roman period, noblemen and officers of the Roman army demonstrated their affinity with Greek education by forming collections of Greek art (mainly fifth to fourth century Athenian), often looted and brought back home. These were also used as symbols of political messages and of military victories. It is, however, during the Renaissance that the contemporary meaning of the museum evolved. It is then that the idea of the public role of the museum also evolved, followed by the notion of the specialist who studies and curates a collection.

In the nineteenth century, the idea of the museum in Greece was closely linked with its role as guardian and tangible evidence of the ancient Greek roots, thus strengthening the modern Greek national identity. Following the emergence of the independent state in 1830, the primary role of the museums aimed at the protection and safekeeping of antiquities, and not so much for their display. Furthermore, unlike most European museums, whose early beginnings were rooted in private collections, Greek museums had a public mission and a strong educational character. They addressed all members of society from the time they were founded, even though they were in practice accessible only to a small educated elite. The new Greek state recognized early in the 1830s the importance of protecting the ancient heritage. It founded the first national museum in 1829 in Aigina (first capital of the state) and established measures for the protection of antiquities. In those early days, several ancient monuments functioned temporarily as museums, like the Parthenon, the Pinakothiki in the Acropolis, and the Stoa of Hadrian in Athens, where the capital moved later. In the rest of Greece, the movable antiquities were collected and guarded in schools, churches,

and public buildings, since there were no funds yet for building museums. The first purpose-built museums in Greece were the Acropolis Museum (1874) and the National Archaeological Museum in Athens (1866–1889).

The first museums in Greece were associated directly with the strengthening of national identity and its links with ancient Greece. The influence of neoclassicism which dominated in Europe, as it was filtered through the modern Greek Enlightenment, emphasized primarily the classical period, even though the collections of the museums covered a period from the prehistoric to the late-Roman times. The belief in the historical continuity of Hellenism and the imitation of the ideals of classical antiquity served the rising middle class, which, influenced by the principles of the Enlightenment, aimed at the reduction of the power of the church and at democratic government. With the arrival of the first modern king of Greece, Otto (or Othon) from Bavaria in 1832, whereby Greece became a new independent kingdom under the protection of the Great Powers (the United Kingdom, France, and the Russian Empire), and the import of western-European political and cultural standards, foreign to the Greek society, the middle class resorted to a sterile historicism and a strong worship of the ancestors.

After World War II there was an expansion and growth of many new museums in Greece; in addition to archaeological museums (which still kept their original role), there were also ethnographic and local history museums and many other types (such as children's museums, theater museums, etc). This expansion of public museums was followed by the creation of many private museums and the involvement of the cultural departments of several banks and private companies and individuals. There has also been a recent expansion of museums of modern and contemporary art.

As the role of science and technology and industrial archaeology became more widely recognized, related museums have also become more widespread in Greece, although their development is much later than in many other European countries. Activities of the Cultural and Technological Foundation of the Greek Bank of Industrial Development (ETVA) and later, of the Piraeus Bank Cultural Foundation, have been instrumental in preserving and promoting Greece's industrial and technological past and in creating related museums.

CURRENT DEVELOPMENTS AND CONCERNS

Currently, a dialog about modern museums' role and ways of operating is becoming more widespread (often influenced by related discussions in the United States and Western Europe). This is evidenced also by an increase in the number of conferences related to museums as well as the number of university undergraduate and postgraduate courses like the undergraduate courses and the MSc in

Cultural Informatics with a Museology option offered by the Department of Cultural Technology and Communication of the University of the Aegean, the interdepartmental MA in Museum Studies of the University of Athens, the interdepartmental MA in Museology of the Aristotle University of Thessaloniki, and the MA in Cultural Management of the Hellenic Open University, specialized journals, (Such as the *Museology Notebooks* [*Tetradia Mouseiologias*] by the publisher Kaleidoskopio, and the online *Journal of Museology*, published by the Department of Cultural Technology and Communication of the University of the Aegean^[5]) and publications. Apart from the theoretical discussions, since the late 1990s there have also been increasing signs of a greater professionalism in the functioning of museums and galleries in Greece; collaboration with trained museologists in the creation of museums, exhibitions, and services; and improved communication with visitors. There have also been encouraging steps to promote professional development and training, where the Greek Committee of the International Council on Museums (ICOM) plays an important role.

In the twenty first century, the opening of the Greek museums to the public is primarily evidenced by educational programs offered by museums, which are becoming more widespread. The early pioneers for these were in many cases private museums (like the Benaki Museum which started its educational programs in 1978, and the Museum of Cycladic Art of the N.P. Goulandris Foundation, from its first year of operation in 1986), but also the Department of Educational Programs of the Directorate of Prehistoric and Classical Antiquities of the Ministry of Culture which was founded in 1985. An important initiative in this direction was the Melina Project, which ran from 1995 till 2003 organized by the Ministries of Culture and Education and the General Secretariat of Adult Education, which supported programs of museums and cultural organizations for primary school pupils (incorporating theater, music, dance and movement, arts, and audiovisual expression).

Another sign of the influence of contemporary museological thinking has been evidenced in the exhibitions created in many Greek cultural organizations since the 1990s. Several of these aim to incorporate audiovisual and interactive media, special lighting, and advanced graphic design in order to support more effective communication of their messages. The use of new technologies is generally spreading behind the scenes to support the management and documentation of the collections as well as for enabling worldwide communication over the Internet and presentation of the collections in different contexts. These developments are followed by an increased interest in the use of standards in all areas of documentation, such as terminology, data organization, and structure. Most Greek museums have some form of computerized collections catalog (even though, with the exception of the Benaki Museum, none of these are available online yet). There have also been initiatives by the Ministry of Culture

for designing and using a common system among state-run archaeological museums. Some Greek museums have also experimented with new technologies for presenting the collections, usually in the form of information kiosks positioned in or near exhibitions, and with electronic publications, such as CD-ROMs and DVDs on the highlights of their collections. The privately funded nonprofit Foundation of the Hellenic World in Athens, established in 1993, was one of the early pioneers in the use of Information and Communication Technology and particularly virtual reality, such as the CAVE-like system, and more recently, the virtual reality Tholos (Dome), an interactive theater with stereoscopic projection inaugurated in 2006, with a seating capacity of 132 visitors. These efforts create an interactive experience for visitors mainly about the ancient Greek past.

NATIONAL ARCHAEOLOGICAL MUSEUM

The National Archaeological Museum is the largest museum in Greece. It was initially founded in 1829 at the Orphanage of Aegina (the first public building built at the first capital of Greece, which housed also the National Library), and its first director was the scholar Andreas Moustoxydis. According to modern museological standards, the first National Museum resembled more a museum storage area and warehouse, as its primary role

was the protection of antiquities. A few years later, in 1833, the Archaeological Service was founded in Athens in order to compliment the Museum's role of protection with those of research, study, and excavation. The Museum was transferred to the new capital of Athens in 1834 and was then named "Central Archaeological Museum," housed initially at the Hephaisteion, the ancient temple of Hephaestus, until 1874 and then changing location several times. It is currently housed in a neoclassical building from the end of the nineteenth century (completed in 1889), which was designed by Ludwig Lange and later remodeled by the German architect Ernst Ziller. During World War II, parts of the collections were boxed, removed for safety and buried. After the war, the redisplay of the collections was organized by the then director Christos Karouzos and his wife Semni Karouzou. The building has undergone several expansions to accommodate the rapidly increasing collections. After its more recent refurbishment, it was reopened in 2004 (Fig. 1).

Although the original purpose of the Museum was to preserve and protect all the finds from the nineteenth century excavations in and around Athens, it was gradually enriched with finds from all over Greece. Its over 20,000 archaeological exhibits cover the beginnings of Prehistory to Late Antiquity in Greece and are organized in five large permanent collections: The Prehistoric Collection includes works of the civilizations that developed in the Aegean from the sixth millennium B.C. to 1050 B.C.

(Neolithic, Cycladic, Mycenaean), and finds from the prehistoric settlement at Thera. The Sculptures Collection shows the development of ancient Greek sculpture from the seventh to the fifth centuries B.C. The Vases and Minor Objects Collection, which contains representative works of ancient Greek pottery from the eleventh century B.C. to the Roman period, includes the Stathatos Collection, a corpus of minor objects of all periods. The Metallurgy Collection includes statues, figurines, and minor objects. And, finally, there is the only Egyptian and Near Eastern Antiquities Collection in Greece with works dating from the predynastic period (5000 B.C.) to the Roman conquest. The Museum functions today as a Special Regional Service of the Ministry of Culture and its five permanent collections are administered autonomously.

BYZANTINE AND CHRISTIAN MUSEUM

The end of the nineteenth century saw the recognition of the role of the Byzantine, late Byzantine, and later period as the bridge connecting historically and culturally antiquity with contemporary Greece. The objects surviving from these periods were treated as testaments to the continuous character of Greek civilization which survived from ancient Greece. In this climate, the Christian Archaeological Society aimed for the creation of a Museum of Christian Archaeology since 1884, when the Museum was initially founded and its director Georgios Lampakis started collecting related objects (mainly religious relics), even though the Museum did not have yet a permanent home. In 1914, the Byzantine and Christian Museum was officially founded as a national organization with Professor Adamantios Adamantiou as its first director, who enriched the collections with objects of national history and art. In 1923, Professor Georgios Sotiriou was appointed the next director and started organizing the collections under scientific principles. In 1930, the government offered to the Museum the mansion of Villa Ilissia, originally the home of the Duchess of Plakentia.

In recent years, a large extension was designed with a basement and buildings partly aboveground, which was then complemented by a varied program of exhibitions and activities. The recently redisplayed collections of the Byzantine Museum show the course of Greek art from the fourth to the nineteenth century. The collections include icons, sculptural works, ceramics, mosaics, manuscripts, and small works representing the artistic production of the Greek mainland and of other regions of the Byzantine Empire.

NATIONAL GALLERY—MUSEUM OF ALEXANDROS SOUTSOS

The National Gallery was founded in 1900 after the bequest of the jurist and art lover Alexandros Soutsos to

the Greek State aspiring to the creation of a “Museum of Fine Arts” a few years earlier. Its first curator was the painter Georgios Iakovidis and it was housed until 1939 at the Technical University buildings (Polytechnion), where the first nucleus of the collection was formed from 1878. After the war, it was housed in several different buildings until it was moved in 1976 to its current purpose-built location. The expansion of the collection and the new needs of the Gallery have led to plans for extending the current space.

The main foci of the collections are twofold: renaissance art (a small but important collection) and the representation of Greek painting through time (from the late Byzantine period until today). Temporary exhibitions are usually supported by sponsorships, which cover about 50% of the Gallery’s budget. The mission of the National Gallery focuses on the enrichment of the collections, the care and study of artworks as well as in “the aesthetic cultivation of the public, the ongoing education through art and the pleasure that it offers, but also in national self-consciousness through the history of Greek art that expresses national life on a symbolic level.” Responding to this role, the National Gallery-Alexandros Soutzos Museum aims to present its permanent collections in a manner that highlights both the evolution of art and the parallel development of the society which it expresses. In order to serve this mission more effectively and expand its activities in the periphery of Greece as well, it has also founded a series of annexes: the Koumantareios Art Gallery in Sparta, the annex of the National Gallery in Corfu, and one in Nafplion which opened in March 2004, as well as the National Sculpture Gallery, inaugurated in 2006 and housed at the former royal stables in the Alsos Stratou in the area of Goudi in Athens.

BENAKI MUSEUM

The Benaki Museum is the largest and oldest museum in Greece operating as a foundation under private law. Its nucleus was the extensive collections housed at the private neoclassical mansion of Antonis Benakis, scion of one of the leading families of the Greek diaspora of Alexandria, which were donated to the Greek state together with the building in 1931.

The Museum collections are organized under the following departments: Greece at the Benaki (which covers Greek cultural objects from antiquity until 1922, aiming to show the continuity of Hellenism through time), Greek artists of the twentieth century (including the Gallery of the Greek painter Nikos Chatzikyriakos-Gkikas and the Studio of artist Giannis Pappas), the Department of Childhood, Toys and Games, Coptic Art, Chinese Art, Pre-Columbian Art, and Islamic Art. The collections also include rich and wide-ranging archives (photographic, historical, performing arts, and modern Greek architecture ones).

Despite various extensions of the original building, the continuously expanding collections, needs of the Museum, and modern museological demands led to a large project of decentralization of services and buildings. This follows the satellite concept with a number of autonomous branches (located at several impressive and in many cases historic buildings around Athens) organized around an initial central core (housed at the original main building, whose displays are currently devoted to narrating the history of Hellenism over time). The projects included the establishment of the New Benaki at 138 Peiraios Street (Fig. 2), one of the central development axes of Athens, at a recently refurbished building, which currently shows only changing exhibitions and performances (art, music, architecture, drama, cinema, dance) and functions as a cultural center, but is anticipated to also house the rare (in Greece) Chinese, African, Indian, and Pre-Columbian collections. Another part of this restructuring and expansion project included the creation of the Benaki Museum of Islamic Art, which is housed in a neoclassical building complex at the historical center of Athens (near the ancient Kerameikos cemetery) that was inaugurated in 2004. The collection of children's Toys and Games will be housed in the Kouloura Building, in Palaio Faliro, a seaside suburb of Athens.

Apart from the high quality and size of the collections, since its foundation, the Benaki Museum has played an important role in the Greek museological scene. It was the first to organize an educational program, a museum cafe, a museum shop, an association of Friends of the Museum, and an Information Technology Department.

Grey Literature [ELIS Classic]

Joachim Schöpfel

Department of Library and Information Sciences (IDIST), GERiico Laboratory Charles de Gaulle University Lille 3, Villeneuve d'Ascq, France

Dominic J. Farace

Grey Literature Network Service, TextRelease/GreyNet, Amsterdam, The Netherlands

Abstract

This entry provides an overview on the definition and evolution of grey literature in the emerging environment of digital resources and open access to scientific and technical information as well as the social sciences and humanities. First, it gives some empirical evidence on the importance of grey literature in scientific publications from different domains, especially library and information sciences (LIS), based on citation analysis. Other topics include the impact of Internet on the production of grey literature, the place of grey resources in open archives and institutional repositories, the development of bibliographic control and standardization, and the difficulties of identification and accessing grey documents. The entry ends with some predictions on the future of grey literature and open questions for research in LIS.

INTRODUCTION

A great part of scientific results are published first and/or exclusively in reports, conference proceedings, pre-prints, working papers, theses, dissertations, personal communications, technical notes, etc. In spite of their widespread differences, all these documents are known by library and information science (LIS) experts as “grey literature” because they share two common characteristics: they are outside of the realm of commercial publishers, and they are rather ephemeral—often poorly controlled by catalogs, databases, and bibliographies.

How important is grey literature for scientific publishing, are there distinctions between the different research domains? What is the usual definition of grey literature, does it change in the environment of digital libraries and New Technologies of Information and Communication (NTIC)? What types of science and technology information (STI) does the term “grey literature” cover, how is it disseminated, how can it be assessed? In which way is grey literature related to and impacted by open archive initiatives? Who does research on grey literature, and what are the frontline topics for LIS research?

The following entry addresses these and other questions but acknowledges that there still remain unanswered questions because of the rapid evolution of information technologies and practices. Nevertheless, we conclude with nine predictions on the future of grey literature.

WHAT EXACTLY IS GREY LITERATURE?

There are several definitions of grey literature, the most common being the so-called “Luxembourg definition,” which was discussed and approved during the Third International Conference on Grey Literature in 1997: “[Grey literature is] that which is produced on all levels of government, academics, business and industry in print and electronic formats, but which is not controlled by commercial publishers.” In 2004, at the Sixth International Conference on Grey literature in New York City, a post-script was added to the Luxembourg definition for purposes of clarification “. . . not controlled by commercial publishers i.e., where publishing is not the primary activity of the producing body.”

This definition in itself contains two of the main characteristics of “grey” resources: On the one hand they are universal and ubiquitous, but on the other hand, they are difficult to identify and to obtain through conventional publishing circuits.^[1] The Luxembourg definition is also vague enough to reflect the problem of determining exactly what a type of literature variously described as “ephemeral,” “nonconventional,” or “underground” really means. To quote two experts from the British Library, “grey literature is difficult to define.”^[2]

Another definition is from the U.S. Interagency Gray Literature Working Group, “Gray Information Functional Plan,” January 18, 1995, that defines gray (or grey) literature as “foreign or domestic open source material that usually is available through specialized channels and may not enter normal channels or systems of publication,

distribution, bibliographic control, or acquisition by book-sellers or subscription agents.”^[3]

In fact, the term traditionally covers three categories of documents—conference proceedings, reports, and doctoral theses—that are often printed in short runs. Nevertheless, the borderline with “white” or “conventional” literature is permeable, since some conference proceedings are published by commercial publishers, as monographs in serial publications or journals, and the same is true for some reports. As for doctoral theses, especially in the humanities and social sciences, some are also found on the commercial publishing market.

However, regarding all the other documents that circulate outside conventional publishing circuits, the lack of “commercial control” raises real problems for academics and scientists as well as for information professionals when it comes to locating and acquiring them. The lack of “commercial control” and promotion also often implies a lack of “bibliographic control.” In other words, these documents are often inadequately referenced in catalogs and databases, so that searches through this category of scientific information require specialized knowledge on sources and circuits.

THE WHO'S WHO IN GREY

Information professionals—including archivists, librarians, researchers, and teachers—have been contributing to studies on grey literature for nearly 30 years now, compiling a rich corpus of articles and, since 1993, international conference papers on grey literature.^[4] In 1985, several European national libraries and information centers founded European Association for Grey Literature Exploitation (EAGLE) to identify and disseminate grey literature. In the 1990s, governmental initiatives in France resulted in particular in the establishment of two national “one-stop shops” for accessing reports of general or scientific interest (La Documentation Française, INIST-CNRS). Other countries have designated “deposit and distribution centers” [such as the British Library^[5] for the United Kingdom or the TIB (German National Library of Science and Technology) Hanover^[6] for Germany] or established portals for scientific reports (such as GrayLit for U.S. Federal Agencies), which was discontinued in 2007.

From 1992 on, Farace, a former member of the EAGLE technical committee founded GreyNet, the Grey Literature Network Service,^[7] which organizes the international conference series on grey literature. Conferences in the GL-Series have since taken place in Amsterdam (1993 and 2003); Washington, D.C. (1995 and 1999); Luxembourg (1997); New York City (2004); Nancy, France (2005); New Orleans, Louisiana (2006); Antwerp, Belgium (2007); and the next in this series—the Tenth International Conference on Grey Literature—

returns to Amsterdam in December 2008. The more than 250 authors and researchers in the field of grey literature, who have contributed over the past years to the above conference programs form as it were the WHOIS in grey literature along with the host and sponsoring organizations, whose financial contributions guarantee the continuity and longevity of research programs and projects in the various sectors of government, academics, business, and industry.

The Textrelease Web site^[4] provides biographical notes for over 75 academics, scientists, and professionals who work and publish on grey literature.

Special tribute should be paid to five outstanding personalities who made lasting contributions to specific areas in the field of grey literature in the four decades from 1960 to 2000:^[8] A.M. Weinberg (the United States), author of the famous “Weinberg Report 2000”; V. Alberani (Italy), organizer of a national program for grey literature; C.P. Auger (the United Kingdom), who provided the first Roadmap of Grey Literature Systems and Services; P. Wattenberg from the German Max-Planck-Gesellschaft, who specialized in the infrastructure of grey literature for the Japanese JICST (now JST, Japan Science and Technology Agency); and A. Zemskov (Russia) from VNTIC, the National Public Library for Science and Technology, where he explored the free access of information and grey literature.

To date, only one monograph has been published on grey literature.^[9] In 1989, in his second edition for Bowker-Saur, Charles P. Auger re-titled his work “Use of Reports Literature” (Butterworths, 1975) to “Information Sources in Grey Literature.” This title change was indicative of the fact that reports were only one type of grey literature among increasing sundry of other types; and that the term “grey literature” was most suited to capture this phenomenon. Auger’s work saw a 4th edition in 1998. Unfortunately, however, in this his final edition, the rise of electronic grey literature was almost completely neglected. TGJ, *The Grey Journal* (ISSN for the print edition 1574-1796) from TextRelease/GreyNet in Amsterdam is the only current journal dedicated to this topic. Since its creation in 2005, some 70 articles were published in the first four volumes. TextRelease/GreyNet also maintained a cooperative publishing agreement with PRQ, Publishing Research Quarterly (2004–2007) whereby the annual spring issue of that journal was solely dedicated to articles on grey literature that originated as conference papers within the GL-Conference Series; and this accounts for another 35 journal articles. Both TGJ and PRQ maintain licensing agreements with EBSCO Publishing, whereby the full-text of both TGJ and PRQ are online, available in the Library, Information Science & Technology Abstracts (LISTA)-FT database. Earlier IJGL, *International Journal on Grey Literature* (ISSN 1466-6189) was edited in 2000 by Emerald (former MCB University Press). However, it ceased publication after the

first volume of four issues totaling 23 journal articles; these articles are nevertheless still available on the Emerald server. Most other articles on grey literature are published in other serials in LIS or journals from other scientific domains such as *The Lancet*, *Marine Policy*, and *European Psychiatry*.

While it is rather easy to identify specific landmarks in the history of grey literature studies, it is perhaps first more constructive to indicate timeframes in which grey literature has developed. Five such periods can be distinguished.

1. They begin with the years leading up to 1979 in which numerous uncontrolled terms such as ephemera, fringe literature, fugitive literature, nonconventional literature, non-published literature, report literature, research outputs, small-circulation literature, unconventional literature, unpublished literature, etc., were coined to capture the growing phenomenon.
2. The period 1980–1990 covered the development and launch of national and international programs on grey literature (1985 is the year in which the European network EAGLE was created).
3. The period 1990–2000 included the creation of GreyNet, the Grey Literature Network Service (1993 is the year in which the first international conference on grey literature was convened).
4. The years 2003–2005 covered the re-launch of the Grey Literature Network Service showcasing new projects in the context of the explosion of digital resources, the movement for open access to scientific and technical information, and the Web2.0 (these research results were presented at GL conferences in Amsterdam (NL, 2003), New York (US, 2004), and Nancy (FR, 2005). This growth occurred notwithstanding the fact that EAGLE and its System for Information on Grey Literature in Europe (SIGLE) database was also terminated in 2005.
5. The current timeframe from 2006 onward is one in which new cooperative research initiatives in the aftermath of EAGLE-SIGLE are on the rise.

One of the recent projects is the OpenSIGLE project,^[10] an initiative powered by INIST to provide access to former SIGLE records in an open source context. In the spring of 2008, GreyNet signed on to the OpenSIGLE Repository in order to preserve and make openly available research results originating in the International Conference Series on Grey Literature.^[11] And, in so doing, the OpenSIGLE Repository has become the intersection of more than 25 years of bibliographic information on grey literature with 15 years of research in the field. Another initiative is the collaboration of researchers in the field of grey literature on institutional levels involving cross-country and international

partnerships. And yet another recent initiative was the pilot for a distance learning course on grey literature for (post)graduate students, one that was accredited by the University of New Orleans (UNO) and which is now available to other academic institutions. These and other such cooperative initiatives were introduced and discussed at the GL conference in New Orleans (US, 2006) as well as the GL conference in Antwerp (BE) in December 2007.

ON THE (RELATIVE) IMPORTANCE OF GREY LITERATURE

Grey literature has a role of its own as a means of distributing scientific and technical information,^[12] and professionals insist on its importance for two main reasons: research results are often more detailed in reports, doctoral theses, and conference proceedings than in journals, and they are distributed in these forms up to 12 or even 18 months before being published elsewhere.^[1] We might add that some results simply are not published elsewhere.

But how do researchers actually use grey literature? One way of evaluating this is to analyze the citations given in their publications. In order to obtain empirical evidence, we present two different approaches: first, results from a Franco-Dutch study launched in 2004 and revisited in 2005 with evidence for different scientific disciplines, and second, results from a small study of bibliographic references published in four different journals in LIS.

Citation Analyses

Let us look first at some results from the Franco-Dutch study^[13,14] which analyzed 64 citation analyses published between 1987 and 2005, citing altogether several thousands references. Table 1 shows the proportion of grey literature cited in publications from different scientific disciplines.

The relative importance of grey literature is largely dependent on research disciplines and subjects, on methodological approaches, and on sources used. In some

Table 1 Proportions of grey literature citations in selected scientific domains

Field	Grey literature citations (in %)
Soil science	14
Biology	5–13
Veterinary medicine	6
Psychiatry (addiction)	1
Psychology	3
Engineering sciences	39–42
Economic sciences	9–17
Sociology	7–9
Education sciences	14–19

fields, especially the life sciences and medical sciences, there has been a traditional preference for conventional distribution media (journals), while in others, such as agriculture, aeronautics, and the engineering sciences in general, grey literature resources tend to predominate.

In particular, public administrations and public and industrial research laboratories produce a great deal of “grey” material, often for internal and in some cases “restricted” dissemination.^[15]

Publications in LIS

For a more accurate idea of the way grey literature is used in LIS, we analyze recently published articles from four representative, refereed LIS journals with impact factor.

Emerald’s *Journal of Documentation* (ISSN 0022-0418) published 13 articles in the first two issues of 2007 (vol. 63), with 472 bibliographic references. About 16% of these references are to grey literature.

The first issue of 2007 (vol. 43) of Elsevier’s journal on *Information Processing & Management* (ISSN 0306-4573) contains 17 articles with a total of 469 references. Of them, 80% cite commercial material (e.g., serials, monographs, and conference series), while the other 20% are grey.

The journal *Information Technology & Libraries* (ISSN 0730-9295) is published by the American Library Association (ALA). The four issues in 2006 (that comprise vol. 25) contain 24 articles with 512 references, 36% of which are to grey literature.

Finally, when we examine the 18 papers comprising the second issue of 2007 (vol. 12) *Information Research* (ISSN 1368-1613), we find 374 bibliographic references, 18% of which are to grey documents. Note that “Information Research” is an international electronic open access journal from the University of Sheffield (U.K.).

Four journals, eight issues, 72 articles with 1827 bibliographic references is not a large sample. Nevertheless, let’s sum up the evidence in the following three points:

Grey literature apparently plays a considerable part in the LIS, accounting on average around 20% of all sources used. This figure may be compared with the citation habits in economics and educational sciences (see above).

Even so, citations to grey material vary widely between different papers from 0% to 50% and more, depending at least in part on subject areas and methodologies.

Most of the noncommercial documents might be identified as unpublished material e.g., doctoral or master theses, reports, legal texts, working papers, lecture notes, Web sites, and even posted messages. This also holds for some conference proceedings and other serial resources, for the identification of the exact nature of the cited material poses difficulties. However, all of these above mentioned types of documents have in fact been published by

what can be referred to as corporate authors i.e., organizations responsible for producing the grey literature, but whose primary activity is not publishing.

ON THE TYPOLOGY OF GREY LITERATURE

To return now to the definition of grey literature, we indicated earlier that the term traditionally refers to reports, conference proceedings, and doctoral theses. We will now take a closer look at what these cover in reality. The SIGLE database has been supplied since the 1980s with information from organizations in several European countries. Its more than 800,000 references are distributed as follows (Table 2).

Reports are the most numerous by far among the different types of grey literature in the SIGLE database. But the “reports” category covers a wide variety of very different documents: institutional reports, annual or activity reports, project or study reports, technical reports, reports published by ministries, laboratories or research teams, etc. Some are disseminated by national and international public bodies; others are confidential, protected, or disseminated to a restricted readership, such as technical reports from industrial R&D laboratories. Some are voluminous, with statistical appendices, while others are only a few pages in length.

In the other categories, citation analyses^[14] offer a tremendous range of grey resources. Besides theses and conference proceedings, they also include unpublished manuscripts, newsletters, recommendations and standards, patents, technical notes, product catalogs, data and statistics, presentations, personal communications, working papers, house journals, laboratory research books, preprints, academic courseware, lecture notes, and so on. GreyNet in fact maintains an extensive online listing of document types, which are categorized as grey literature (Table 3).

However diverse, these documents all share one thing in common, they contain unique and significant scientific and technical information that is often never published elsewhere. The lack of descriptive referencing and adequate circulation is therefore, as we have said earlier, a real problem for scientific communication.

Table 2 Distribution by the types of documents referenced in the SIGLE database

Document types	Proportion (in %)
Reports	62.7
Theses	31.7
Conferences	2.3

The Internet, however, is now altering the entire landscape. Not only because of changing user behavior, but also, and especially, because more and more grey literature is being published on the Web. As one study from

the German Centre for Information in the Social Sciences has pointed out,^[16] the switch from paper to digital does not necessarily mean that more grey literature is appearing. Instead, the Internet has radically changed access and distribution methods, accentuating the ephemeral and volatile nature of grey literature. This same study also drew attention to the fact that many journals and the journal articles contained therein can be categorized as grey literature i.e., where publishing is not the primary activity of the producing body. The fact that in Europe, for more than two decades the SIGLE database did not identify journals and journal articles as grey literature may account in part for the apparent neglect of these two types of grey documents.

And yet, another special type of grey material is also likely to gain more importance. Until now, raw data—the basis for many scientific publications—are widely unpublished and inaccessible. Today, public research organizations are starting to develop national and international strategies for the control and archiving of these files, the data, and statistics (scientific data infrastructure or eScience, see Hey and Trefethen^[17]). The principle of open access to datasets is generally accepted (astronomy, life science, physics, etc.) but major Scientific, Technical, and Medical (STM) publishers, because of their historical role and responsibility in the dissemination of scientific results, claim that such data should become part of their portfolio of added value products much like scientific journals and articles. Up until the mid-1990s, the Dutch Social Science Information and Documentation Center (SWIDOC), an institute within the Netherlands Academy of Arts and Sciences (KNAW), maintained a paradigm, whereby current research information and statistical datasets were linked to reports and other grey literature. Unfortunately, this model was abandoned. However, with the rise of repositories such as OpenSIGLE, where attachments and links to a metadata record allow access to the enriched publication, this paradigm can now be fully realized. The coming years will determine who will gain control over the deposit and dissemination of these materials. Will it be the public bodies or corporate information companies, who win out? The question is not only political but economic as well.

GREY LITERATURE IN OPEN ARCHIVES

Since 1994, the movement toward open access to scientific information has been crystallizing around various initiatives to promote open archives.^[18,19] The first preprint server, ArXiv, set up by P. Ginsparg at Los Alamos in 1991 was a means for distributing research results organized by and for physicists, without intermediaries. This initiative was entirely independent of any commercial circuit for scientific publications.^[20] In this sense, the server

(which today contains over 410,000 documents) corresponded exactly to the definition of grey literature.

However, the case is more complex. “Preprints”^[21] would not have existed without the prospect of “print”—in other words, ArXiv would not have existed without scientific journals. Ginsparg’s aim was simply to circulate results quickly and immediately. The point then was not to bring commercial publishing into question, since Ginsparg did not offer any alternative to the peer review system still run by the conventional publishing circuit. ArXiv was in fact creating a kind of symbiosis between grey literature and traditional publishing, which was linked to the highly specific organization of the nuclear physics community.

But the crisis that has hit scientific journals along with the appropriation of new technologies of information and communication has together helped to turn the means of distribution into an alternative model of scientific publishing. This model has two objectives, one being economic: in that it offers a cheaper alternative to scientific publications by increasing pressure on STM publishers introducing competitive and parallel publishing channels. The other being an administrative one: by facilitating control over scientific production issuing from various research organizations and universities by way of identifying and evaluating publications through a central database.

Given the methodological and interpretative diversity among different scientific communities, one may well wonder whether a system that has operated for more than 15 years in physics will be equally effective in other fields, especially in view of the constraints induced by research evaluation. However, we are seeing derivatives of that system in the social and human sciences spearheaded by organizations such as the New York Academy of Medicine (NYAM) with their Grey Literature Report,^[22] the Centre for Information on Low External Input and Sustainable Agriculture (ILEIA) with their LEISA e-magazine and database,^[23] and the New York University (NYU), School of Social Work with their Web-based resource Information for Practice.^[24]

What is the part played by grey literature in this new environment? The international “Directory of Open Access Repositories” (OpenDOAR), established by the Universities of Nottingham and Lund,^[25] identifies 1,115 different sites, including 250 from the United States and 94 from the United Kingdom (June 2008). OpenDOAR indexes some categories of grey literature, including theses^[26] and conference proceedings, but also learning objects (especially university lectures) and research results (data sets). Table 4 shows the number of open archives that contain certain categories of grey literature.

At first sight, these figures seem to suggest that grey literature is relatively well represented in open archives: 50% contain doctoral theses, and about 40% contain conference proceedings, reports or working papers. However,

Table 4 Presence of different document types in the OpenDOAR archives ($N = 1115$)

Document types	Number of archives	% of OpenDOAR sites
Theses	585	51
Unpublished	533	46
Conferences	427	37
Multimedia	262	23
Special	193	17
Learning objects	166	14
Datasets	62	5
Reports	56	5
Software	26	2
Working papers	16	1

the picture becomes less clear with an analysis of archive descriptions, which show that the number of sites explicitly dedicated to grey literature is considerably smaller: less than 20% are identified for doctoral theses, only 5% for reports, and just 1% for conference proceedings. Probably, a lot of grey material is hidden in categories like “special” (letters, images, sound, sites, etc.), “unpublished” (preprints, etc.) or “multimedia.” Observations made at the Seventh International Conference on Grey Literature in 2005 indicate that these documents are often swamped within the sheer mass of documents that are deposited in archives and/or difficult to identify. The development of open archives does not therefore seem to have altered the situation of grey literature to any great extent.

To sum up, we observe a steadily growing number of open archives that (also) contain grey literature. It is nearly impossible to give an overall number of grey documents in these repositories. And even if it were possible, those documents are not currently representative of the national output of scientific and technical information. Moreover, there are even fewer repositories in smaller countries, especially outside of Europe and North America; and, non-English material remains until now largely invisible and un-retrievable.

IMPROVING “BIBLIOGRAPHIC CONTROL”

We said earlier that the lack of “commercial control” of grey literature implies a lack of “bibliographic control.” In other words, “grey” documents are often inadequately referenced in catalogs and databases.^[27] This does not mean that there are no standards or recommendations for cataloging reports, conference proceedings, theses, and so on. However, contrary to the situation with journals and books, the absence of commercial stakes has contributed to a (relative) “success” of the rules that have been set out.

The way in which the different types of grey literature are referenced still depends more on choices made

by the bodies that produce, collect, or distribute these documents, rather than on any national or international standard (ISO, ISBD). The failure of the International Standard Technical Report Number (ISRN) is symptomatic in this respect. France, having been the only country with an active ISRN agency (INIST) for several years, eventually had to agree to the ISO, thus abandoning the ISRN. The only remaining exception in France concerns doctoral theses submitted to French universities for which the academic union catalog *Système universitaire de documentation* (SUDOC) imposes a uniform bibliographic format.

On a European level, input requirements for the SIGLE database forced the network's member countries to attempt to harmonize their "grey" resources around a single SGML format. But input to SIGLE ceased in April 2005, and its EAGLE association has gone into liquidation.^[28] The predictable outcome is that each organization will be returning to its own referencing methods and rules abandoning any kind of uniform bibliographic control.

The rapid development of the Internet, and its ever-multiplying online resources, is affecting bibliographic control in two ways.^[16] In one way, this "wild growth" is speeding up the decline in the application of formal and controlled standards, with the risk that grey literature is becoming "even more greyish." However, in another way, the same risk has also boosted global awareness of the need to define a few minimal data—called metadata^[29]—in order to provide a framework for referencing digital documents.

Examples include: a project aiming to adapt the Dublin Core to reports^[30] or doctoral theses; the French "Thèses Electroniques Françaises" (TEF) initiative, which is working on a set of metadata and a single XML schema,^[31] the "Text Encoding Initiative" (TEI) designed to develop and recommend, at international level, common tagging standards that are independent from IT upgrades,^[32] and the creation in 2005 of a TEI support centre for Europe located in Nancy, which will also address the matter of grey literature.

The problem of poor standards and lack of uniformity in referencing documents deposited in institutional archives was the reason why JISC (Joint Information Systems Committee)^[33] was established in the United Kingdom in 1993. Its task was to look into the interoperability of these archives and to describe their resources in order to facilitate identification by end-users.

One final example: after the Seventh International Conference on Grey Literature in 2005, P. de Castro and S. Salinetti from the Istituto Superiore di Sanità in Rome initiated the International Steering Committee on Grey Literature (GLISC), which would develop recommendations (the "Nancy Style") for the production and distribution of scientific and technical reports as well as other grey literature. The second version of the document is now published on the Web,^[34] with translations into French, Italian, German, and Spanish.

This last example is symptomatic in some ways of the problem of bibliographic control of grey literature. It is an international issue to which national responses have only brought partial solutions, thereby actually increasing the diversity of data and the difficulties involved in identifying and locating documents. Since there are no set commercial issues at stake, improved referencing will always be dependent on the initiatives and willingness of producing and distributing organizations steered by a few committed information professionals.

ACCESS AND DISSEMINATION

Identifying, locating, and obtaining grey literature is generally not easy—and this is inherent to its nature. To get some idea of the problem, readers might attempt a search for some of the reports, working papers, Web pages, conference proceedings, and doctoral theses cited by the authors of the four LIS journals mentioned earlier in this entry.

For 20 years, the SIGLE database offered a solution at EU level, insofar as its partner organizations were under obligation to keep referenced documents at their end-users' disposal via lending or document delivery services.

Users today are faced with a huge variety of sites, archives, catalogs, and databases, which makes searches for "grey" information not only painstaking but sometimes prohibitive—taking into consideration the linguistic difficulties involved.

In view of the rapidly changing face of STI within the digital environment, all the major traditional centers collecting and distributing grey literature, such as the British Library, the Canadian Institute for Scientific and Technical Information,^[35] the TIB in Hanover, and INIST have undertaken to develop free access services to these documents, especially theses and preprints, but also reports and other types of grey literature.^[36]

What is now needed are portals and search tools that are specifically dedicated to "grey" documents. Elsevier started to index in their SCIRUS search engine NASA reports and dissertations, MIT courseware, working papers and communications from a number of institutions, as well as theses in electronic format from the United States, China, India, and other countries. The Office of Scientific and Technical Information (OSTI) at the U.S. Department of Energy (DOE), hosted the GrayLit Network's unique science portal of technical reports from U. S. Federal Agencies. Now that this portal has been discontinued, we look to OSTI/DOE's Keynote Address at the Tenth International Conference on Grey Literature (Amsterdam, December 2008) in order to see if and how the global science gateway, WorldWideScience.org and its multilateral governance structure, the WorldWideScience Alliance will incorporate scientific and technical grey literature (including the social sciences and humanities).^[3] A European comparative initiative

from members of the former EAGLE association to launch a metasearch engine dedicated to grey literature collections is still in draft stage.^[37] In the meantime, users have no other choice but to conduct searches on their own using whatever means at hand (Google), or to remain with the search services provided by established organizations.

The short history of EAGLE indicates some challenges of grey resources. Initially funded by the Commission of the European Communities in order to provide access to European grey literature and improve bibliographic coverage,^[1] EAGLE was faced 20 years after its creation with major problems that lead to its liquidation.^[28] The SIGLE database offered no solutions for online cataloging, meta-data harvesting, links to full-text, and other resources. National input became increasingly unrepresentative of the national production, and was continuously decreasing while digital documents were not referenced. And last but not least, the economic model of its nonprofit, low-budget association did not allow for necessary strategic decisions, because further investment for the development of the database was not provided by the European Union or by the member institutions.

THE FUTURE OF GREY LITERATURE

Grey literature will remain a challenge for information and documentation professionals as well as an interesting field for research activities in at least six areas:

The need for a new definition: The traditional definition of grey literature needs to be further refined and/or redefined by way of an accurate analysis of new means of access and distribution, in line with Mackenzie Owen's observation that "Grey does not imply any qualification (but) is merely a characterization of the distribution mode."^[38] What we see is that the current "Luxembourg" definition moved from emphasis on the acquisition of grey literature to the production of grey literature. And now, the definition should reflect both.

The need for an economic model: Despite the absence of "commercial control," collecting, distributing, and searching grey literature all come at a price, which may in fact be much higher than for journal article and book searches. To date, there is no clear economic model in this area and further analysis is needed in terms of investments, direct and indirect costs, acquisition prices, and so on. The case of EAGLE underlines the need for public funding and a sustainable economic model to guarantee the bibliographic coverage and full-text, enriched dissemination of grey literature.

The need to oversee archiving practice: New technologies of information and communication facilitate resource archiving in general, and there is strong incentives from the "open access" movement. Nevertheless, the question of "who should archive what, where, when, and for how long" has remained largely unanswered.

Aware of information policy and the concomitant financial aspects involved, answers are rather urgently needed, even if they were to now address only part of grey literature resources.

The need for a new "value chain": In the Netherlands, Roosendaal has in the past few years, been examining the process whereby universities re-appropriate publications. In his work, he highlights the radical changes taking place in the "value chain" of scientific publication.^[39] This type of research and evaluation of scientific publications brings to the forefront major issues in the context of emerging STI trends. What is the future of peer review? Which "quality label" applies to working papers or scientific communications on blogs or in open repositories? Does the community approach of Web 2.0 offer a viable solution for the need for quality standards of noncommercial STI materials? The impact of new technologies in information and communication on the dissemination of nonconventional literature is a complex matter, and the potential field for research is vast. To date, research and analyses have only broken ground giving way to a vast and virtually untapped field of investigation.

The need to clarify the legal aspects: In our study, the issue of intellectual property rights in grey literature has been deliberately left aside. Nevertheless, the legal status of grey resources and rights in their use (deposit, archiving, distribution, etc.) is (another) major challenge for the future of this form of STI publishing. The national and international legal environment is evolving rapidly, and all restrictions, exceptions, and technical constraints [Digital Rights Management (DRM), interoperability, etc.] of the new laws on intellectual property, author's rights, and copyright also apply to grey resources. Nevertheless, very few documentary analyses have addressed legal aspects in the field of grey literature and their subsequent economic consequences. This issue, however, will be taken up in a plenary session during the Tenth International Conference on Grey Literature (Amsterdam, December 2008). While the outcome of this forum may not be conclusive, much needed groundwork will have been covered.

The need for education and training: At the Sixth International Conference on Grey Literature (New York, 2004), the results of an online survey in which 102 respondents participated not only indicate that an increasing number information professionals involved in grey literature are also involved in teaching and instruction but also they were in agreement (69.2%) with the statement that grey literature constitutes a field in information studies. Over the past years, training courses, guest lectures, seminars, and workshops have been organized by information professionals on the topic of grey literature. Most of these endeavors have undoubtedly had some impact on this field of information. As mentioned earlier in this entry, an accredited college course on grey literature was carried out via UNO's distance education program in the fall semester 2007. And, it has been rescheduled for the spring

2009 semester. Education and training is fundamental to the future of grey literature—not only for LIS students and their instructors but also for information practitioners in government, business, and industry as well.

While the above six areas of consideration remain as yet to be fully addressed, there has been considerable effort on the part of INIST and GreyNet over the past 15 years to use the results of research compiled within the International Conference Series on Grey Literature,^[13,14] and, at the same time, to involve the existing pool of GL authors and researchers, who have contributed to its information and knowledge base. Without them, the future of grey literature would have little or no direction based on empirical data and would be simply *speculative*. It would have remained among the myriad of uncontrolled terms listed earlier in this entry.

CONCLUDING REMARKS

In concluding our current review on the state of grey literature, we might offer the reader some prospects in further need of reflection.

It seems likely that:

1. Grey literature will not disappear, but will continue to play a significant role alongside commercial publishing. Our research has led us to believe that information discovery into the various types of grey literature available in print and electronic formats is ever increasing.
2. The borderline between “grey” and “white” (commercial) literature will become increasingly indistinct, particularly in an environment that is moving toward open access to STI. However, in our limited research we find that the approaches and appropriations to these two kinds of publications are still quite distinct.
3. The proportion of “grey” documents published on the Web will continue to increase. We see this development closely linked to the production of grey literature in e-environments, as well as to retrospective activities leading to republication.
4. The Internet will encourage a greater diversity in the types of “grey” resources available (raw research results, notes and personal comments, lectures, newsletters, product catalogs, etc.). Also as our own research indicates, grey journals and the articles contained therein even now challenge reports as being the mainstay of grey literature.

It also seems likely that:

5. Bibliographic control of grey literature will remain problematic despite the trend toward standardization of digital documents. We find that this has everything

to do with the application and use of standards, which are in transition.

6. Open archives will offer more appropriate services and functions for at least some segments of grey literature i.e., preprints, doctoral theses, and reports. We mention these three types of grey literature, because they have come to form special collections making them more visible in and for repositories.
7. Some organizations—especially in the public sector (e.g., national libraries and STI centers) but also in the private sector (e.g., Elsevier, Google, etc.)—will develop tools and services to aid in the efficient exploitation of grey resources on the Web. This in all likelihood is based on the response by such organizations to our research efforts.

However, it seems unlikely that:

8. Searching and collecting grey literature will become as straightforward as it is for journals and books in the traditional publishing sector. We adjudge that the increase in grey over commercial publications is the main explanation for this.
9. New tools for collecting, depositing, and archiving will make grey literature less ephemeral and volatile than in the past. Our research indicates that until an organization formulates a policy on grey literature backed by budget appropriations, the implementation of technology cannot be guaranteed and thus the environment in which grey literature has coexisted in the past will remain unstable in the likely future.

HathiTrust

Rick Anderson

University of Utah, Salt Lake City, Utah, U.S.A.

Abstract

HathiTrust is a partnership of major research libraries working together to create and maintain a digital archive of the human cultural record. Its programming includes not only a digital library but also a growing array of programs and services to facilitate scholarship.

HathiTrust is an international partnership of research libraries formed for the purpose of preserving, curating, and making access available to the record of human knowledge.

HathiTrust was formally created in 2008, but its roots can be found in conversations that were taking place among research libraries in the early 2000s, a period during which it was becoming clear that cooperative, large-scale digitization of printed documents might soon become technically and fiscally feasible. A watershed moment came at the inception of Google's massive Google Print initiative, which within months had been expanded to encompass what came to be called the Google Library Project.

The Google Library Project is a partnership between Google and a number of major research libraries including those of the University of Michigan, Harvard University, Stanford University, and Oxford University, as well as the New York Public Library.^[1] Under the agreements struck with these libraries, Google agreed to digitize portions of the libraries' collections; partner libraries received a copy of all digitized works. The libraries negotiated the right to share those digitized copies with other libraries, thus laying the foundation for the broad collaboration that underlies HathiTrust.

The Google Library Project eventually became an international initiative, attracting participants from Germany (the Bavarian State Library), Spain (Complutense University of Madrid), France (Bibliothèque Nationale de Lyon), and Japan (Keio University) among other countries.^[2]

Among the earliest and most extensive libraries participating in this project were those affiliated with the Committee on Institutional Cooperation (CIC), a consortium of research libraries affiliated with universities in the Big Ten athletic conference, plus the University of Chicago.^[3] In 2005, the members of this consortium began making plans for a shared repository to hold the digitized copies of books from their collections—not only for the purpose of permanent preservation but also to make the content of those books more readily available to readers and

researchers. In 2008, the libraries of the University of California System joined the shared initiative, and the resulting program was redubbed HathiTrust.^[4]

THE “HATHITRUST” NAME AND INITIAL GOALS

“Hathi” is the Hindi word for “elephant,” and it was chosen at the outset of the collaborative project to “(underscore) the immensity of this undertaking” as well as to “evoke memory, wisdom, and strength,” according to John Wilkin, who was at the time associate university librarian at the University of Michigan and the first executive director of HathiTrust.^[5] Early in the process of forming the coalition and defining its mission, the partner institutions settled on a set of six initial goals:

1. To build a reliable and increasingly comprehensive digital archive of library materials converted from print that is co-owned and managed by a number of academic institutions
2. To dramatically improve access to these materials in ways that, first and foremost, meet the needs of the co-owning institutions
3. To help preserve these important human records by creating reliable and accessible electronic representations
4. To stimulate redoubled efforts to coordinate shared storage strategies among libraries, thus reducing long-term capital and operating costs of libraries associated with the storage and care of print collections
5. To create and sustain this “public good” in a way that ensures the greatest availability of materials to the public but offers additional value to members, mitigating the problem of “free riders”
6. To create a technical framework for the repository that provides significant centralized functionality, such as full-text search, but also supports distributed development of tools and services to allow partners and nonpartners to meet specific access needs of their user communities^[4]

SHORT- AND LONG-TERM FUNCTIONAL OBJECTIVES

In accordance with the goals outlined above, the HathiTrust partners also agreed on a set of short-term and long-term functional objectives. These were not meant to define the scope of HathiTrust's mission, but rather, in Wilkin's words, to help "articulate goals for a quickly emerging organization, a way to give some initial direction until other mechanisms could create a more nuanced roadmap." These objectives were

Short Term

1. Creation of a page-turner mechanism
2. Branding
3. Format validation, migration, and error-checking
4. Development of application programming interfaces that would allow partner libraries to access information and integrate it into local systems
5. Access mechanisms for persons with disabilities
6. A public discovery interface
7. The ability to publish virtual collections
8. A mechanism for the direct ingest of non-Google content

Long Term

1. Compliance with required elements in the Center for Research Libraries' (CRL) Trustworthy Repositories Audit and Certification (TRAC) criteria and checklist
2. Robust discovery mechanisms, such as full-text cross-repository searching
3. Development of an open service definition, to make it possible for partner libraries to develop other secure access mechanisms and discovery tools
4. Support for formats beyond books and journals
5. Development of data-mining tools for HathiTrust, and use by HathiTrust of analysis tools from other sources^[6]

PRESERVATION AND ACCESS

From the beginning, a central tenet of the HathiTrust program was the twinned imperatives of preservation and access. The purpose of the initiative was never to create a "dark" archive but rather to focus simultaneously on two overarching goals: first, both curating and safeguarding the digitized documents; second, making them as freely and easily available as technology and the law would allow. To this end, the HathiTrust partners determined early on that—while it would recognize and respect all legal constraints around copyright and other intellectual

property law—the program would not accept for deposit documents whose original owners wished to keep them inaccessible, where access rights could be lawfully granted. Books and other documents that are in the public domain are, thus, freely available for the general public to view and download (though HathiTrust members have enhanced access capabilities, as will be discussed below), whereas documents currently protected by copyright are available for full-text searching; search results do not include views of full-page texts but instead indicate the number and locations of occurrences of the search terms across titles in the HathiTrust database, enabling the user to see which books contain significant occurrences of those terms. The researcher can then pursue access to the relevant books through his or her local library or bookstore.

CONTENT

As of January 2014, the HathiTrust digital collection contained just under 11 million volumes, comprising approximately 5.7 million book titles, 286,000 serial titles, and 3.8 million pages of text. Of its 11 million volumes, 3.5 million are in the public domain. Just over half of the books are in languages other than English; more than 400 languages are represented in the collection. While the great majority (roughly 82%) of the volumes in HathiTrust were originally published in the twentieth or twenty-first century, the collection includes books several centuries old, including more than 25,000 books published during the seventeenth century and just over 1,000 from before 1500. (Though it is worth noting that roughly 350,000 volumes in the collection are of either not-yet-determined or indeterminate date.) A very large majority of the volumes in the collection deal with disciplines in the humanities and social sciences, especially history and literature, in a wide variety of languages.

Because HathiTrust's collection is built on digitized materials taken primarily from large North American research libraries (which comprise the roughly 115-member Association of Research Libraries, or ARL), there is significant and growing overlap between HathiTrust content and the physical collections housed in most ARL libraries. In 2011, a white paper prepared by Constance Malpas of OCLC on the feasibility of "cloud-sourcing" research library collections noted that, for example,

in June 2009, approximately 20% of titles in NYU's Bobst Library (as measured by holdings in WorldCat) were duplicated in the Hathi repository; by June 2010, the rate of duplication has increased to about 30%.^[7]

Wilkin subsequently found that this pattern was "remarkably constant" across ARL libraries. Writing in 2011, he observed that as of June 2010

nearly every ARL library could depend on finding approximately 31% of its collection online in HathiTrust. The rate of overlap (continues) to grow; by June 2011, I estimate the overlap rate to have hit a median of about 45%, and (to) reach something like 50% overlap early next year.^[6]

MEMBERSHIP

To join HathiTrust, an institution must submit summary information about its print holdings. This information is used to determine the amount of overlap between the institution's holdings and the contents of the HathiTrust collection; that overlap partially determines the institution's membership fee, which is calculated according to two formulas. The first combines an equally distributed share of the cost of hosting public-domain content with a sliding share (based on local holdings overlap) of the cost of hosting in-copyright materials. The second is a cost multiplier designed to generate a surplus sufficient to support new services and programmatic infrastructure for the organization. As of January 2014, the multiplier is 1.5, though the Board of Governors will review that value periodically.

Members of HathiTrust have the option (though are not required) to contribute digital documents of their own to the collection. As of January 2014, there are no additional costs associated with deposit, as long as the materials submitted are formatted and submitted according to HathiTrust specifications.^[8]

A significant benefit of membership consists in enhanced access to the public-domain materials housed in the collection (that are not subject to third-party restrictions). While these materials are freely available to the general public for online discovery and reading as well as printing and download, nonmembers can only print and download such materials page by page. Users affiliated with member institutions are able to download and/or print entire books from the public domain collection as single .pdf files.

Another member benefit is the ability to make in-copyright materials available to users who have disabilities that make use of printed materials difficult or impossible; if the library in question currently holds (or once held) a physical copy of an in-copyright book held digitally by HathiTrust, that library can obtain a full .pdf copy of the book from HathiTrust on behalf of such a user, subject to a set of guidelines and restrictions designed to keep the program in compliance with copyright law. (HathiTrust provides one set of guidelines for institutions in the United States and another for those in Canada.)

HathiTrust also provides member institutions with limited access to materials falling under the provisions of Section 108 of the copyright law—"where the print copies

of the works are damaged, deteriorating, lost or stolen, and a copy is not available on the market at a fair price."^[9]

REPOSITORY CERTIFICATION

In March 2011, HathiTrust was certified by the CRL as being compliant with TRAC criteria.^[10] This certification came as the result of a one-year audit that examined HathiTrust's organizational infrastructure, digital object management practices and technologies, technical infrastructure, and security practices. CRL found HathiTrust to be most solidly in compliance with regard to the latter category and most in need of improvement (though still certifiably robust) in the first; ongoing certification requires HathiTrust to report progress every two years in several areas, including significant changes in system architecture, new policies, additions to content, financial activities, and significant organizational events.^[11]

GOVERNANCE

HathiTrust was originally chartered for a five-year period, from 2008 to 2012, with an expectation of formal review of its governance and structure in the third year.

Prior to 2012, HathiTrust was governed by an Executive Committee, which was composed of library administrators from its founding institutions: two members each from Indiana University, the University of Michigan, and the University of California system. In addition, the Committee included HathiTrust's executive director and one member drawn from another CIC institution. The Executive Committee was guided by a Strategic Advisory Board, the chair of which acted as a member of the Executive Committee *ex officio*. This arrangement was intended to be provisional until a new governance structure could be put in place with broader input from the HathiTrust membership. The organization contracted with Ithaka S&R to conduct a three-year review of the organization's progress.

In late 2011, HathiTrust held a Constitutional Convention for the purpose of creating a new and more permanent governance structure and set of bylaws. Over the course of two days, delegates from all HathiTrust partner institutions and consortia considered and voted on ballot proposals dealing with such issues as an approval process for development initiatives, the disposition of U.S. government documents, and the new governance structure.^[12]

The governance structure settled upon in the Constitutional Convention provides for a Board of Governors consisting of 13 members: six appointed by the founding HathiTrust institutions, six elected by the membership, and the Executive Director (in a nonvoting role). Of these 13 board members, five (including the Executive Director,

ex officio) serve as an Executive Committee. All board members are elected to a three-year term; however, in order to establish a staggered rotation of members (and thus ensure some degree of continuity), members of the inaugural board were assigned a variety of term lengths from three to five years.

INITIATIVES, TOOLS, AND SERVICES

In addition to serving as a permanent repository and offering search and download capabilities, HathiTrust has developed a variety of services designed to add value to the hosted content. Such development is ongoing; as of this writing, notable tools and services include:

HathiTrust Research Center

The HathiTrust Research Center (HTRC) is the research arm of HathiTrust and makes possible computational use of the HathiTrust digital library for nonprofit and educational researchers. A joint venture of Indiana University, the University of Illinois Urbana-Champaign, and HathiTrust, the HTRC provides a secure environment in which researchers can use text mining and other data-intensive research techniques to interrogate and analyze digitized texts on a massive scale. Currently, the HTRC environment allows researchers to conduct such analysis of public-domain titles, but HathiTrust is working toward agreements that would allow such use of in-copyright works as well.

HathiTrust has created e-mail listservs, a User Community wiki, and a portal for workset construction, and has hosted two annual 1-1/2-day “UnCamps” for those in the research community interested in learning how to make use of the HTRC’s offerings.^[13]

mPach

mPach is a project of the University of Michigan’s Michigan Publishing program, in collaboration with the University of Michigan Library’s Digital Library Production Service. It is designed to provide support for born-digital publications, and to that end, in collaboration with HathiTrust, mPach will provide a modular platform for the creation and publication of open-access journals and will offer integration with other open journal applications such as Open Journal Systems. As of January 2014, completion of the project is projected for sometime between October and December of that year.^[14]

Zephir

Zephir is a bibliographic metadata management system developed for HathiTrust by the California Digital Library.^[15] It is the first component of HathiTrust that has

been developed and will be managed by an entity outside of the University of Michigan.

Copyright Review

HathiTrust member institutions have been working since 2008 to identify materials in the collection that are in the public domain. In some cases, this is easy to determine based on standard bibliographic data points, but in many cases such a determination requires significant work. This effort has resulted in the public availability of hundreds of thousands of titles.

Government Documents

In 2013, HathiTrust began a project to preserve and provide access to a comprehensive collection of U.S. federal government documents (which are in the public domain by definition). As of January 2014, this project is still underway, beginning with the creation of a formal registry of those documents including information about which of them are available in digital formats.^[16]

Shared Print Monograph Archive

In an effort to help libraries reduce their long-term storage and preservation costs, HathiTrust is developing a framework for a distributed network of print monograph archives; the network’s holdings will correspond to HathiTrust’s digital collection.

DPN Participation

The Digital Preservation Network is a network of digital repositories working to “ensure that the complete scholarly record is preserved for future generations.”^[17] HathiTrust is working with that initiative to help define its technical, business, and administrative models. In November 2013, it announced its intention to become a “replicating node” in the DPN.^[18]

ISSUES AND CONTROVERSIES

Because the HathiTrust is built on a multimillion-volume repository of digitized books, most of which are still under copyright, there have been questions and issues surrounding both the legality of the original digitization project (carried out primarily by Google, Microsoft, and the Internet Archive) and of HathiTrust’s subsequent use of the collection.

Authors Guild v. Google

In 2005, Google was sued by the Authors Guild of America and the Association of American Publishers (AAP),

both of whom asserted that Google's digitization project constituted massive copyright infringement.^[19] A finding for the plaintiffs in either or both of these cases would have had significant implications for HathiTrust's ability to continue providing access to its collection. The lawsuits were eventually consolidated and the parties reached a settlement; however, the proposed settlement was rejected and a separate settlement was subsequently reached between Google and the AAP. The Authors Guild persisted with its suit, which was dismissed in 2013. As of January 2014, the Authors Guild intends to appeal that decision.

Authors Guild vs. HathiTrust et al.

In 2011, the Authors Guild filed suit against HathiTrust and the governing bodies of its founding universities, asking for "injunctive and declaratory relief" from what it characterized as "the systematic, concerted, widespread and unauthorized reproduction and distribution" of the digitized books in HathiTrust's collection. The lawsuit did not ask for damages, but rather asked the court to affirm and declare the illegality of HathiTrust's actions and to impound the digital books.^[20]

One aspect of the case came to dominate public discussion; this was HathiTrust's plan to make "orphan works" available online to those who have "the right to check out these works from the Library's print collection for scholarly and educational purposes."^[21] Orphan works are generally defined as titles that are under copyright, but whose copyright holder is unknown. Since orphan works are almost invariably out of print, they are unavailable for purchase in the primary book market (though used copies may be available in the secondary market). Michigan's justification for providing free—though limited—access to the full text of the digitized orphan works to its faculty and students was that since the copyright holders were unknown or could not be located, since the books were not commercially available anyway, and since access would be limited to a controlled population of Michigan-affiliated readers, the provision of them was very unlikely to harm any stakeholder in the work. In addition, HathiTrust publicly offered to curtail providing access to any orphan work whose copyright holder identified himself or herself and submitted a form provided for the purpose.

The program began in 2011 with the posting of a list of orphan works identified as candidates for this treatment; the list was to remain live for 90 days, during which copyright holders were invited to contact HathiTrust either to formally grant permission or to withhold it. Following the 90-day period, the books would be made available, but copyright holders could subsequently contact HathiTrust and request a takedown at any point thereafter, and HathiTrust promised to honor that request.^[22]

The Authors Guild, however, objected quickly—noting, among other things, that it had succeeded without too much effort in identifying and locating rightsholders to several titles on HathiTrust's list of orphan works. Michigan subsequently removed some titles from the list and then announced a suspension of the program. In a public statement, the institution said that "the close and welcome scrutiny of the list of potential orphan works has revealed a number of errors, some of them serious. This tells us that our pilot process is flawed." The statement expressed the Michigan Library's intention to "create a more robust, transparent, and fully documented process," at which point it would "proceed with the work, because we remain as certain as ever that our proposed uses of orphan works are lawful and important to the future of scholarship and the libraries that support it."^[23]

In October 2012, the court dismissed the Authors Guild's suit, finding in particular that its claims regarding the orphan works project were "not ripe for adjudication," given that the project had been stopped too soon for its ultimate nature and impact to be assessed.^[24] The Authors Guild is appealing the decision.

Health Science Professional Literatures and Their Users

Cheryl Dee

School of Library and Information Science, University of South Florida, Tampa, Florida, U.S.A.

Jocelyn Rankin

Centers for Disease Control and Prevention Library, Atlanta, Georgia, U.S.A.

Abstract

Information behaviors of the major health sciences professionals are described, in particular those of physicians, nurses, and public health workers. Biomedical researchers are mentioned to illustrate new approaches to information. Continuing barriers to information use include information overload and lack of time, but there is also increasing use of Web resources and growing self-sufficiency. Strong preferences are apparent for information resources that are convenient, accessible, customized, and “just in time.” Challenges remain in motivating busy health care professionals to adopt routine information-seeking strategies. Future work should focus on embedding information in workflows by using new technologies and new workers such as informationists.

The dynamics between health care professionals and their information use forms the basis for bridging the gap between the biomedical knowledge base and the use of it in daily medical practice and clinical decision-making. Health care professionals’ information needs typically require responses within a short time frame. They need information that is credible, current, and relevant to the specific case at hand. While the knowledge base of the health sciences is the biomedical literature, primarily the journals, additional sources such as collegial expertise, continuing education programs, drug information resources, and various online knowledge services augment the published literature. Library services and technologies that connect the health care professional with this knowledge base in a meaningful and efficient way must be grounded in information-seeking and information-use studies.

Today’s health professionals span many areas of practice. This entry focuses primarily on information behaviors of three major professional groups: physicians, nurses, and public health workers. Biomedical researchers who support clinical practice are mentioned briefly because their transforming approach to information may well foreshadow the future information behaviors of all health scientists. Allied health professionals are not addressed in this entry as there is still a need for a solid base of information studies in most of these disciplines.

PHYSICIANS

The 760,000 physicians in the United States are found largely in medical practice; they also work in medical education, health care administration, and research. Physician education programs add to this workforce through 8500

residency programs that train 11,000 residents. The 126 schools of medicine maintain enrollments of more than 70,000 students, and the 20 schools of osteopathic medicine educate another 13,500 students.^[1–3]

During the last 25 years, research has contributed to a better understanding of information needs and information-seeking practices of physicians. The published literature in the 1980s and early 1990s set the stage for subsequent studies on physicians’ information-related behaviors. Much of this research focused on physicians’ preferred information sources, whether patient care questions were being answered, and whether physicians’ information needs were being met. These studies showed that physicians frequently asked colleagues for information, used their personal libraries, and consulted textbook sources.^[4–6] Covell found that many information needs were not recognized by practicing physicians, and that others went unanswered.^[7] Osheroff analyzed information requests during clinical teaching and found that there were frequent requests but that often these requests required synthesis of patients’ information and medical knowledge and therefore were difficult to fulfill.^[8] Gorman showed how the biomedical literature could answer primary-care information needs, while Dee’s study of rural physicians proposed a new information-retrieval system that would build on the positive factors related to collegial consults and would provide concise, relevant, and synthesized answers to specific questions in a format conducive to rapid comprehension and immediate use.^[4,9]

Numerous factors influence physicians when they consider using an information resource. These factors include convenience of access, habit, reliability, quality, speed of use, and applicability.^[10] Also availability, credibility, currency, rapid delivery, compatibility with their own and their colleagues’ experience, and cost in time, effort, and

money have been found to affect physicians' preferences for information resources.^[6,11-14] The organizational culture and an emphasis on use of the biomedical knowledge base, along with searching skills, may be leading factors stimulating use of online systems by health care professionals.^[15]

Common barriers to health professionals' information seeking include lack of time to search, information overload, the belief that there is likely to be no answer, and lack of urgency.^[10] When searching for answers to physicians' questions, Ely developed a taxonomy of obstacles encountered. Of the 59 obstacles identified, six were considered particularly prominent, including not having adequate time to find information, difficulty framing a complex issue into an answerable question, difficulty selecting the best search strategy, failure of a seemingly appropriate resource to answer the question, uncertainty in knowing when all the relevant evidence had been gathered, and lack of prepackaged syntheses of multiple bits of evidence.^[16]

After a slow uptake of the use of technology, physicians are now employing and benefiting from the Internet and online information resources. An important early study of use of the National Library of Medicine's MEDLINE database by physicians for clinical problem-solving found that MEDLINE searches were performed by and for physicians to meet a diversity of clinical-information needs. Physicians reported that in situations involving individual patients, rapid access to the biomedical literature via MEDLINE was at times critical to a patient's care, and that such rapid access favorably influenced patients' outcomes.^[17] More recent studies are showing that Web-based information resources are playing an increasingly central role in the delivery of care. The use of multiple online information resources has been shown to enhance the accuracy of answers provided by experienced clinicians to typical clinical problems.^[18] And Bennett found that the average time spent by physicians on the Internet had doubled between 2001 and 2003, with the primary reasons being to access the latest research, locate information in a specific disease area, and find information for patients' problems.^[19] While information overload on the Internet remains a barrier, physicians are now more skilled in using preferred Web sites, and they are encountering fewer technical challenges and becoming increasingly confident that they will find needed information.^[20] Patterns of use of Web-based resources may vary somewhat by physician specialty, as was shown in a study comparing family physicians with specialists' use of the Internet. Family physicians were more likely to seek patient-oriented information while specialists searched the literature and exchanged information with colleagues. Almost half of the family physicians involved in this study utilized handheld computers, primarily for drug reference.^[11]

The emphasis on the practice of evidence-based medicine (EBM), a formal process that enables patient-care

decisions to be based on "the conscientious, explicit and judicious use of current best evidence" that has been compiled through systematic research,^[21] has led to new efforts to convey the biomedical knowledge base to the point of care. The need to overcome barriers to accessing the evidence base was underscored by the Institute of Medicine's report on improving the quality of our nation's health care system.^[22] There are formidable challenges in locating the best evidence and applying it at the point of care given the ever-growing amount of biomedical literature and its sometimes conflicting viewpoints, the distance between the evidence and patient care, and the variables inherent in individual patient cases. The market place has stepped up with several electronic evidence-summary services. In a small study of EBM summary databases, Schwartz found that slightly more than half of clinical questions could be fully or partially answered, and that these answers often did modify physicians' opinions and influence patient care. However, the time spent in searching for answers was greater than most clinical settings would allow.^[23] When an online evidence system was readily available to health professionals in Australia, it was used by almost half of the clinicians. Use was shown to be associated with patient care, particularly hospital admissions, often influencing clinical decision-making.^[18]

Slawson proposes that while patient care based on evidence is important, EBM at the bedside is not yet always feasible. Therefore medical school and residency curricula also need to emphasize effective information management. The three skills needed are the abilities to select the correct tools for staying up-to-date; to find the right "just-in-time" information that is appropriate, easily accessed, and speedily available as well as usable at the point of care; and to combine the best evidence with patient-centered care, considering both the needs and perspective of the patient.^[24]

Another strong influence on physicians' information needs and behaviors is the growing use of the Internet by their patients. Fox estimates in the 2008 Pew Internet & American Life Project that between 75% and 80% of Internet users have looked online for health information. Fox's comparison of the Pew estimate with Harris Interactive's latest data on health-information seekers shows that 81% of Internet users and 66% of all adults have sought health information online. Pew's data show that 67% of Americans expect to find reliable information about health or medical conditions online. When asked where they would go the next time they need health or medical information, 46% of Internet users said they would use the Internet and 47% said they would contact a medical professional. Overall (i.e., Internet users and nonusers), 31% of all Americans say they would try to find health information online, while 59% say they would contact a medical professional.^[25]

As a result, more patients are better informed about their health conditions, and they ask their physicians more

questions. When searching the Internet, they may be supplementing information received from their physicians, looking for a second opinion, discussing sensitive issues with patient groups, or looking for information for another person or for a child.^[26] Web-based resources for consumer health information require careful evaluation. Credible Web sites are maintained by medical professional groups such as the American Academy of Family Physicians; by health associations such as the American Cancer Society; and by patient advocacy groups. The award-winning National Library of Medicine's MedlinePlus Web site provides a well-organized portal to health care information on a wide range of topics.^[27] Physicians' information needs that relate to communications with their Internet-literate patients will only increase in the coming years as the United States meets the challenge of improving the overall health literacy of the general population.^[28]

NURSES

Nurses make up the largest professional group in the health care community, numbering more than 2,200,000 in the United States. About 80% of these registered nurses work part-time or full-time. With 1500 schools offering registered nursing degrees, close to 100,000 new graduates are added each year to the workforce.^[1] However, the nursing shortage continues to be severe and, with the aging of those in nursing profession, the shortage is only expected to increase in the coming decade. The shortage is also a reflection of the limited capacity of the nation's training programs as compared with the demand.

These nursing professionals' health information needs are broad and varied addressing both their clinical and educational needs. A small pilot study demonstrated that nurses' information needs are indeed quite different from those of physicians.^[29] Research has shown that nurses often need information for their practice and those with advanced degrees may recognize these information needs more frequently than their colleagues. Their information requirements are typically patient-centered, frequently relating to nursing procedures and protocols.^[29-32] Cogdill found that nurse practitioners' information needs most often related to drug therapy and diagnosis.^[33]

As is the case with other health care professionals, nurses appear to prefer obtaining information from resources that are convenient and accessible.^[34] Colleagues are favorite resources for nursing information. Print materials are another group of preferred resources of information, including nursing textbooks and journals.^[33-36]

The literature however, indicates an underutilization of the available nursing literature. As with other health care professionals, nurses find that time is a leading obstacle to using the literature. Additional barriers include lack of value for research in practice, lack of organizational

support, lack of understanding of electronic resources and their structures, difficulty in accessing research materials including electronic resources in clinical areas, and lack of critical appraisal and searching skills.^[31,37] The need to achieve a supportive culture in the profession for use of the literature is reinforced in McKnight's study, which found that many nurses believed that taking time to read published information on duty was not only difficult, but perhaps also ethically wrong.^[30] For these and other reasons, nurses do not pursue all of their information needs. Nurse practitioners self-reported that they followed up on slightly more than half of their information needs; however, a second measure in the same study indicated that significantly fewer information needs were actually pursued.^[33]

Mid-1990s research found that electronic sources of information such as CINAHL and MEDLINE were increasing in popularity with nurses, but usage reports differed from study to study. Estabrooks suggested that database searching as a source of nursing information appeared to be much less appealing to some nurses than did personal experience and colleagues. While nurses' Internet and e-mail use at home has increased, Internet use at work is low despite adequate workplace access.^[38] In a national survey, Pravikoff found that nurses acknowledged their need for information, but they had greater confidence in consulting the Internet or colleagues than they did in using bibliographic databases such as PubMed or CINAHL.^[31]

Ready availability of information resources and training do appear to facilitate greater use by nurses of the knowledge base. A recent report of an evaluation of the information-seeking practices of nurses before and after access to a library's electronic collection of information resources showed that at the inception of the project, nurses used colleagues and print textbooks or journals to satisfy their information needs. However after 1 year with access to the electronic library, 20% of the nurses had begun to use the electronic resources.^[36] A smaller but similar project initiated by the same library suggested practicing clinical nurses will use online information resources with appropriate training and accessibility.^[39] In a clinical setting with unlimited access to the Internet, nurses used and accessed the Internet for a combination of work and nonwork-related activities. Information enthusiasts emerged who facilitated use for other nurses. Again, training was a recommendation from this study.^[40] Recent research showed that more nursing students than clinical nurses used online databases, including CINAHL and PubMed, to locate health information, and that nursing students were more likely than clinical nurses to report performing a database search at least one to five times a week.^[35] Confirming this consensus in the value of computer instruction, Secco found that good computer and literature searching skills were positively associated with greater use of electronic information and also with

expectations that desktop information would improve practice.^[32]

Low use of information resources has led nursing leaders to question the readiness of the nursing profession to transition to a more evidence-based practice. The need for evidence-based practice and access to the latest information is particularly critical in the nursing profession where, as Pavikoff noted, more than two-thirds of those practicing graduated prior to 1990.^[31] A systematic review of the literature found that predictors of research use by nurses could be categorized according to beliefs and attitudes, involvement in research activities, information seeking, professional characteristics, education, and other socioeconomic factors. Only the beliefs and attitudes category was actually substantiated in the reviewed research.^[41] Milner found that clinical nurse educators, clinical nurse specialists, advanced nurse practitioners, and nurses working in research leadership positions are important in facilitating evidence-based practice. However, Milner found also that not all nurses in those categories have the necessary critical appraisal skills and research knowledge to use research effectively in practice.^[42] Pravikoff concluded that significant changes are needed through a multifaceted approach involving students, educators, clinicians, and administrators before nurses in the United States fully implement evidence-based practice.^[31]

In the era of evidence-based practice and increased accountability for all health care professionals, facility with searching and using electronic information resources is an important skill for nurses. However, many nurses still do not have the necessary skills to pursue their information needs. Health sciences librarians can play an important role in providing instruction to nurses in accessing and evaluating the literature.

PUBLIC HEALTH

Public health is distinct from other medical fields in that its focus is on the population as a whole, rather than on the individual patient. Information requirements are therefore quite different but nonetheless critical. Ready access to the public health knowledge base is fundamental to achieving the nation's goals established decennially^[43] to improve health, including finding the best solutions to community health needs, promoting healthful lifestyles and disease prevention, and providing informed responses to public health issues. And in public health emergencies, public trust requires rapid, well-informed responses to health threats, often of unknown origin and continually unfolding over hours and days.

The public health sector itself is a complex amalgam of federal, state, and local units, health care institutions and providers, as well as many health-related organizations and advocacy groups. The workforce is drawn from at

least 35 professions as well as 20+ other job categories. Examples of public health workers included public health medical officers, nurses, environmentalists, nutritionists, sanitarians, inspectors, and laboratorians. Workers' educational backgrounds range from advanced degrees and specialty training to technical backgrounds to those with high school diplomas and on-the-job training. The United States, which is currently experiencing a severe shortage in the public health workforce, has an estimated 450,000 public health workers. Less than 1% are epidemiologists, biostatisticians, or infection-control specialists who have critical responsibilities in the post-9/11 world.^[44] Efforts are underway to better define the workforce, accelerate recruitment into the field, and to implement more systematic enumeration strategies.

While there is general consensus on the critical need to make information accessible to the public health community, there have been few formal studies of information needs. These studies can be confounded by the public health workforce's diversity, worker-role variation and overlap, and the fuzzy boundaries of the field. As noted by Revere and colleagues in their literature review, it is not possible to design a comprehensive needs assessment that would neither yield informative data nor design a one-size-fits-all information system solution.^[45]

Because information services are often unavailable, information needs, when they occur, may not be recognized by public health workers.^[46] When recognized, there may be lack of awareness of what information is available and how to search for answers. A Norwegian study showed that while public health workers value research-based information, they do not appear to identify scientific information as a resource for questions encountered in daily practice.^[47] Along with lack of awareness there are other barriers including difficulty in finding the needed information given the breadth of the field, general information overload, limited access to computers and licensed online resources, lack of search skills, limited ability to appraise information quality, and lack of time.^[48,49]

A few studies have examined the types of information used by public health workforce segments. LaPelle found that six categories of information were needed: early reports on new risks and preventive behaviors; early reports on public health practices and programs; information on evaluated interventions; synthesized information about public health threats and practices; published research including systematic reviews and meta-analyses; and evidence-based guidelines.^[49] In looking at five types of public health workers, Rambo found needs for tools to connect with experts; to get updates on legislative issues; and to find structured information about datasets, best practice resources, templates for frequently used applications, and synthesized knowledge-based information.^[50] Other studies have examined specific groups of workers, such as Dobbins' study of public health decision-makers,

in whom there was a strong preference for executive summaries and systematic reviews.^[51]

Like the workforce, the public health literature is diffuse and appears in many disciplines. There is no single index or database that serves the field. While the National Library of Medicine's PubMed database continues to strengthen its public health content, often other databases are required to locate needed information. As noted by Howes,^[52] 44% of the Medical Library Association's list of Core Public Health Journals^[53] and 38% of the University of Massachusetts Lamar Soutter Library's list^[54] are not indexed in MEDLINE. Alpi, in her overview of the major resources for searching in the public health field, notes that the challenges include the range of resources along with the lack of public health indexing terminology in many databases.^[55] A useful compilation of free public health databases is provided at the University of Massachusetts' Evidence-Based Practice for Public Health Web site.^[54] Examples of specialized resources include the National Library of Medicine's Health Services/Technology Assessment Text (HSTAT) database^[56] and the Centers for Disease Control and Prevention's human genome epidemiology (HuGE) knowledge finder.^[57]

In addition to the journal literature, influential white papers, government reports, policy, and opinion papers are important information sources in public health. This gray literature can be discovered at the Web sites of federal and state government health agencies and public health organizations. The New York Academy of Medicine Grey Literature Report captures many public health documents.^[58] A search for statistics, which are frequently sought in public health, should begin at the Centers for Disease Control and Prevention's National Center for Health Statistics Web site.^[59]

As in medicine, there is growing emphasis in public health to use scientific evidence to guide policy making and program planning. Evidence-based public health faces challenges that are different from those of evidence-based medicine: there is considerably less evidence available; the study designs typically cannot match the rigor of controlled clinical trials; population studies generally require a longer time; the workforce has less professional training; and decisions to act on evidence are made by teams as opposed to individual practitioners.^[60] Because public health is interdisciplinary and because a significant portion of its knowledge base lies outside the scope of traditional databases, gathering the evidence for systematic reviews and meta-analyses is difficult.^[61,62] However, a body of public health evidence is beginning to emerge. The *Guide to Community Preventive Services* is the leading source for evidence-based public health best practices.^[63] The well-regarded Cochrane Collaboration includes a Cochrane Health Promotion and Public Health Field group that promotes systematic reviews, identifies new studies, and explores methodology issues in the public health literature.^[64] The Canadian Institutes of Health is sponsoring a

broad-based initiative to assist with the production, dissemination, and application of public health research evidence in Canada.^[65] One outcome is a centralized online registry of systematic reviews, meta-analyses, and evidence-based summaries that are relevant to public health interventions.^[66] The European SPHERE (Strengthening Public Health Research in Europe) project is an example of a recent project to examine public health research publications in order to identify new research priorities and to develop ways to facilitate the integration of research findings into public health policy.^[67]

Providing information services to the public health workforce has fallen outside the mainstream of library services. Where once there were many state public health libraries, only a handful remain. Very few states have formal arrangements for library and information services for their public health workers. A landmark national conference in 1998 assembled stakeholders, highlighted the need for better information services for the public health community, and initiated discussions about solutions.^[48] Progress is now being made in better supporting the information needs of the public health community. One notable result of the 1998 conference was the formation of the Partners in Information Access for the Public Health Workforce, which has developed a public-private collaboration to augment access to and use of information by public health workers at the state and local levels.^[68]

BIOMEDICAL RESEARCHERS

Underpinning the practice of medicine is a large community of clinical and biomedical researchers and scientists. While not practitioners of health care, these researchers contribute to the field by discovering the new knowledge that advances the practice of medicine. Their recent approaches to research are transformational, heralding enormous developments in information systems and the information sciences that will eventually permeate other health care professional groups. Advances in technology and large-scale national and international collaborative research efforts are driving these changes, affecting both the way scientific information is generated and the way it is communicated, particularly in the burgeoning fields of molecular biology and genomics.

While colleagues remain an important information resource for these researchers, scientific discovery is now often derived from databases rather than laboratory bench experimentation as was the case for much of the last century. Primary information needs are increasingly being met by complex nonbibliographic databases that constitute the new knowledge base.^[69] The success of the Human Genome sequencing project and the recent Framingham Heart Study data release illustrate the power of large collaborations to generate new findings.^[70] A leading provider of new research tools is the National

Library of Medicine's National Center for Biotechnology Information (NCBI) that provides a growing list of new resources such as their Entrez databases and the NCBI Map Viewer.^[71] Other examples of new approaches to information include ExPlain, a gene expression analysis platform, and Collexis, a knowledge management and text-mining tool.^[72,73]

Biomedical researchers are often self-sufficient information users and do use traditional information resources, valuing both online journals and a well-organized library Web site that makes locating information more efficient than an Internet search engine such as Google or Yahoo.^[74] However, additionally these researchers work collaboratively, using Web 2.0 methods for rapid dissemination of scientific information. They also work together to build new databases. They require new tools for mining the biomedical literature and the large shared datasets, and tools for synthesizing their retrievals in order to discover relationships and generate new hypotheses.^[75] The current emphasis on translational research, that is moving from science to practical application in health care, highlights the need for new workflows, interoperable data repositories, infrastructure and statistical tools for meta-analyses, integrated ontologies, and other approaches that enable collaborative work and data analysis.^[76] The challenge for health sciences librarians is to become proficient in the new tools and new ways of managing, accessing, and integrating biomedical research information, particularly as many of these strategies may become standards for all health care information.

CONCLUSION

While researchers and academicians are traditionally more facile in using the biomedical research knowledge base than health care practitioners are, a growing trend toward self-sufficiency in information seeking is apparent in the larger health sciences community. Additionally, the need for "just-in-time" clinical evidence at the point of care was emphasized in the findings of a large medical center's information-needs study.^[77] The literature is showing that many health care professionals now expect information services customized to their professional information needs, preferences, and patterns of use.^[74]

The emerging solution to customized services at the point of need appears to employ both technological and human interventions. As Bakken pointed out, an informatics infrastructure is essential for evidence-based practice. This infrastructure must include standard terminologies and structures, electronic information resources, data exchange standards to enable transfer of information across heterogeneous systems, processes that enable evidence appropriate to specific patient cases, and informatics competencies. Among the challenges to achieving this goal are building a persuasive business case; achieving

consensus in describing, organizing, accessing, and archiving information resources; designing clinically relevant information-retrieval strategies; and integrating evidence-based processes into the clinical setting and organizational structure.^[78] Davidoff and Florance have argued that in addition to informatics tools, a new informationist specialist is needed as a full member of the clinical team: a professional who specializes in information, who possesses information science, informatics and domain knowledge, and who works outside the library in the health care setting.^[79] Model informationist programs are now emerging in clinical programs as well as in health policy, public health, biomedical research, and other related domains.^[80]

An understanding of each client group's unique information needs and behaviors will result in the development of clearly targeted products and services. Customized services include both technology tools and embedded librarians that together enable successful and seamless integration of information resources and services into the workflow of health care professionals.

Historical and Archaeological Sites: Development and Preservation

Robert B. Pickering

*Gilcrease Museum, and Museum Science and Management Program, University of Tulsa,
Tulsa, Oklahoma, U.S.A.*

Abstract

Historic and archaeological sites provide windows to life in the past. The sites are the in situ repositories of the human activities. Studying these sites helps this and future generations understand the past and our links to it. Preserving these sites honors those who came before and strengthens our connections to our roots. Sites may be as grand as an historic district or an architectural treasure, or as simple as a small campsite used by ancient hunters. Yet, each has an important story to tell about people in the past.

INTRODUCTION

Historic and archaeological sites are important places. Something happened there. Perhaps it was an event that changed history and is the subject of legend and lore. Other times, such sites are small and the people who created the site are nearly forgotten. However, large or small, famous or obscure, historic and archaeological sites are incredibly important windows on the past. They are our history, our heritage, and our link to the people who came before us.

An object, whether from the past or present, can tell a story. The recent obsession with forensic sciences demonstrates how trained researchers use their knowledge and skills to turn something as seemingly insignificant as a hair into a powerful clue to a past event. Archaeologists sometimes call this process “reading” an object. Any object made by humans can be analyzed as to its means of manufacture and its use. Indeed, objects have a “life cycle” from manufacture through use to abandonment. Determining what has happened to the object after abandonment also can be determined from telltale changes to the object. Many times, these processes are natural processes of decay and destruction that leave their own signatures.

If history can be deduced from a single object, then an historical or an archaeological site has even greater potential for revealing past human behavior. The site provides the context for interpreting objects; the locus of activity at which the objects were used. Perhaps there is a progression of understanding here. An object has a specific and limited function. A group of objects found together may reveal the activity in which the objects were used. The site reveals the holistic picture of the human behavior that used the objects and provides information on the who, what, when, and where that helps researchers look back in time to reconstruct entire events and ways of life.

REVEALING THE SITE

Historic and archaeological site museums have multiple functions. At a minimum, they preserve the record of the past in its original location and they present a story for today’s students of the past. Revealing the story told by these sites often requires the skills of many kinds of scientific and historical researchers. The tasks often begin with precise and careful examination of the site to determine the details of the human-made structures, whether forts, cliff dwellings, a 200-years-old barn, or the remains of a small campsite used by nomadic hunters thousands of years ago (Fig. 1).

Once the site has been mapped to include the natural features and human-made structures, then decisions will be made about how to take care of those structures. Do structures or buildings need stabilization, renovation, reconstruction, or to be left alone? The term “stabilization” means to make the structure as safe as possible with the least change necessary. Today’s conservation ethic, whether in an historical or archaeological context, is that modern changes should be visible and reversible so that future generations of researchers and the public will be able to differentiate between the original structure and any modifications made to it. The reason for making sure that modern changes are visible recognizes that some interpretation is involved in any reconstruction. Over time, the reconstruction may be thought to be original and thereby confuse scholars and the public. As new data is collected, details of the original structure may impact future reconstruction efforts. Each new generation of scholars needs to be able to distinguish between the “original” and the “reconstructed.” Making the distinctions obvious allows each new generation of scholars and researchers to use new methods, tools, and materials to start from the original more easily and efficiently.

Fig. 1 Prehistoric sites such as Legend Rock have been used by a succession of pre-European cultures. Such sites provide powerful experiences for today's visitors but also must be protected from vandalism.

Renovation and reconstruction implies that efforts will be made to enhance the original structure, perhaps bringing it back to the way it looked when it was being used. Historic houses often have been renovated through time so that the visitor has the experience of being in a "living house" not an old musty and abandoned one. Historic site specialists do not always agree on the extent to which renovations or reconstructions are acceptable. Some historic site specialists prefer to make as few alterations or additions as necessary to provide safety for the structure and the people who work in or visit it. In other cases, the goal is to let the visitor see and experience the site as it would have been at the time it was in use. Both of these perspectives can be seen around the world at various houses, forts, and historical places (Fig. 2).

Historic Oak Park, Illinois, was the home of Frank Lloyd Wright and the location of many of the houses he designed. Many towns, such as Santa Fe, New Mexico, or

Fig. 2 Galena, Illinois, has protected sections of the town to create an historic district that keeps its nineteenth century look.

Charlotte, North Carolina, have entire historic districts of period buildings that are being preserved but also used for contemporary purposes. On the world stage, the great cities of Rome, Beijing, Bangkok, Jerusalem, and Mexico City just to name a few, have extensive districts of historic importance that are still part of the urban milieu. Cities often have strict rules that dictate what kinds of materials or physical changes are allowed in order to maintain individual buildings and the look of the entire district. However, the importance of historic sites is not universally appreciated. As cities strive to modernize, particularly national capitols and centers of industry, whole blocks and quarters are sometimes razed to accommodate the needs of current city dwellers. Beijing's preparation for the 2008 Olympics was an excellent example. While the needs are real, the loss of precious historic resources should not be taken lightly.

Archaeologists have a slightly different challenge when it comes to inventorying archaeological sites. By definition, most archaeological sites are buried by centuries or millennia of debris and natural forces. There are many sites that are known by their aboveground presence, but in fact are simply part of much larger sites that are under foot. Throughout the world spectacular aboveground archaeological sites such as Stonehenge in England, the Pyramids of the Giza Plateau and Saqqara in Egypt, Greece's Parthenon, Peru's Macchu Picchu, Mexico's Teotihuacan, and Nan Madol on the Pacific Island of Pohnpei have attracted countless generations of the curious. Today, these sites often are sources of national pride and sometimes considerable generators of revenue.

Yet, these same sites sometimes become targets of intentional destruction. The massive Buddhas of Bamiyan in Afghanistan were destroyed because they represent an earlier religion that is not accepted by some of the current residents of that country. Sometimes, archaeological sites become pawns in contemporary geopolitical affairs.

The great city of Cahokia, on the Illinois side of the Mississippi River across from St. Louis, is no less monumental but differs from many of the world sites in that it was constructed entirely of earth, not stone. Between about 1050–1200 C.E., Cahokia included well over 100 mounds, a great plaza, and extensive housing areas. Cahokia's largest human-made structure, Monk's Mound, can be seen towering above the trees. Its base covers an area larger than the base of the Pyramid of the Sun at Teotihuacan in Mexico. In past decades, excavation was the main method archaeologists used to find buried sites (Fig. 3).

Archaeology is a destructive science. Revealing a buried site requires excavation to see it in detail. Excavating destroys the context. Excavation exposes the buried structures and objects to environmental factors that destroy them much more quickly than if they had been left in the ground. Today, most archaeologists are keenly aware that archaeological sites are like endangered species: If we do

Fig. 3 Monk's Mound at the site Cahokia (the St. Louis Arch in the background), has been encroached up by modern urban development.

not preserve them, they will disappear. Therefore, archaeologists are very careful about what they choose to excavate. Large-scale excavations today must consider not only excavation, but a broad spectrum of data collection and recording, object care, and stabilization of the site. When excavation is initiated, a multidisciplinary team of scientists and technicians are often required so that the record of the site will be as complete as possible and will be preserved through time.

Today, noninvasive tools such as ground penetrating radar, aerial photography with special films and cameras, and magnetometry let archeologists "see" underground structures without having to resort to excavation. Thanks to the technological advances, the need to conduct expansive and expensive excavations to identify architectural features is no longer necessary. In recent years, robotic technology has played a role. Within the Great Pyramid at Giza, there are small shafts that extend out from the tomb chamber. Many theories have been presented as to their function. Using small robots with lights and cameras to explore these shafts might provide new insights into the shafts form and function. Egyptian authorities review

proposals such as these and always have the best interest of the monuments and sites in mind.

Whether in the historical or archaeological context, mapping is only the initial step in creating a great site that can be accessed by the public. Historians and scientists representing many different specialties will analyze the site to determine what actually occurred there. Geologists and soil scientists will help the archaeologist understand what kinds of natural geological formations and processes are important to the site's history. Specialists in conservation, photography, and statistics help preserve and document each piece of the past. Educators and interpreters work with the researchers to help them develop the stories, activities, and information banks which are available to the public. Today, it is common for many of those interpretations to be available on the Web or through other electronic media. This incredible technology makes it possible for people to experience the site, virtually, even if they cannot visit it in person. The experience is not the same, but it is still valuable.

Human beings lived in North America for at least 12,000 years before Christopher Columbus arrived. Some archaeological evidence suggests that North American human history may span 20,000 or more years and that there were numerous waves of migration that brought people to this continent.

In Africa, Asia, Europe, and some other parts of the world, people and even prehuman hominids have lived on the land for longer periods of time. Unfortunately, contemporary human populations often like to live in the same areas as did earlier cultures.

Here then is a conundrum. If people have been here for all those thousands of years and have lived all across the landscape, should we preserve every site that is found? On a shorter timescale, is every old building, farm site, or construction created by humans important enough to save for the future? While it is true that in many ways, each site is unique and definitely each site tells a story, it isn't necessary—it isn't possible—to save all of them. If we did, there would be no land available for this generation and future ones to build their lives. At the same time, is it good enough just to record these sites through images, documents, and to salvage artifacts from those sites, knowing that the bulldozers will destroy the sites? No, every culture needs and wants to preserve the best of its past and its heritage. Disregard for the past would make us a people without a past: a culture with no roots connecting us to previous generations of people and entire cultures that came before us.

SAVING IMPORTANT SITES

Who determines what is worth saving? Does anyone actually decide that some historic or archaeological sites can continue to deteriorate under natural conditions or the

quick destruction of bulldozers? These issues are common in local communities and also on the national level. In recent decades, many important Civil War battle sites in the United States have become threatened by real estate and mining development. These pieces of ground saw some of the most terrifying battles in a war that defined this country. To see them become shopping malls was more than many people could bear. The Civil War Preservation Trust was founded to stop the destruction of these historic sites. Their annual report, *History Under Siege*, provides insight into the strong emotional connections that many people feel toward our heritage and shows how individuals can become actively engaged in the preservation effort.

The Civil War Preservation Trust is one of many such preservation organizations that work to save important historic and archaeological sites. From passionate individuals to local historical societies to national organizations, many Americans have joined the preservation efforts. Moreover, many of these sites are not just protected, they are interpreted through many kinds of on-site programs and museums that help visitors understand what they are seeing. Many also go beyond providing just the visual experience; they actually create activities to engage the visitor at the site.

In some countries, the preservation of past sites became an issue long ago. For example, in 1666, Sweden passed a law to protect prehistoric sites and antiquarian monuments. The American Antiquities Act of 1906 was the first significant American law to keep archaeological sites from being desecrated and destroyed. The law was a result of a grassroots effort to preserve important sites from America's pre-European past. Devil's Tower in Wyoming was the first monument designated under the Act by President Theodore Roosevelt. This site is sacred to many Plains tribes including the Crow, Kiowa, Lakota, Cheyenne, and Arapahos. Each tribe had their own name for and legend regarding Devil's Tower. Many of them focused on an association with the bear. Bear Lodge, Bear Lair, and Grizzly Bear Lodge are examples.

In the late 1800s as Euro-American populations increased in the American Southwest, an interest in the region's living and ancient Indian cultures increased. Sadly, some of the interest focused on looting at grand sites in Chaco Canyon, Mesa Verde, and smaller sites across the arid landscape. Without protection, these monuments of the past would become pockmarked fields of destruction. Acts such as the early Swedish law and the American Antiquities Act are courageous efforts to stop the destruction (Fig. 4).

In 1966, the National Historic Preservation Act became law and with it, the National Register of Historic Places (NRHP). This law protects not just single buildings, but also entire sites and even districts that have historical importance. This act also pertains to archaeological, as well as historical sites across the country. Each state has a

Fig. 4 The fine architecture of Mesa Verde is the most visible remnant of ancient life ways that have evolved into the Southwestern Pueblo cultures of today.

State Historic Preservation Officer (SHPO) who is responsible for site protection and overseeing the process by which additional sites are proposed for protection. The SHPO's office normally maintains data on all of the archaeological sites that have been found in the state.

According the NRHP Web site, the criteria for protection are:

The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association and:

- A. That are associated with events that have made a significant contribution to the broad patterns of our history; or
- B. That are associated with the lives of persons significant in our past; or
- C. That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic values, or that represent a significant and distinguishable entity whose components may lack individual distinction; or
- D. That have yielded or may be likely to yield, information important in prehistory or history.” <http://www.nps.gov/history/nr/listing.htm>(accessed August 2008)

The Archaeological Resources Protection Act (ARPA) of 1979 expands the protection of archaeological sites beyond the American Antiquities Act (1906) and more clearly defines what kinds of activities are prohibited. ARPA also provides for incarceration and larger financial penalties for convicted violators. The law was enacted:

to secure, for the present and future benefit of the American people, the protection of archaeological resources and sites which are on public lands and Indian lands, and to

foster increased cooperation and exchange of information between governmental authorities, the professional community, and private individuals.

<http://www.nps.gov/archeology/tools/Laws/arpa.htm> (accessed August 2008)

Many archaeological sites are living sites upon which individuals, families, or entire communities conducted the myriad activities that constituted their lives. Such landed sites can be very large, with boundaries changing through time as the use of the site changed. Moreover, the living sites may represent large numbers of people doing very different things within the boundary of the historic site.

UNDERWATER SITES

Shipwrecks are underwater archaeological sites that tell important stories, too. Recovery of the 17th Swedish *Vasa*, England's *Mary Rose* sinking in 1545, and the *Atocha* which sank in 1622 off the Florida Keys have yielded not only spectacular artifacts, but also insights into their special history and times. Closer to our times, the sinking of the *Titanic* was a traumatic event that continues to generate interest and intrigue. The *Titanic* has not been salvaged, although it has been explored through remote devices. Indeed, the rush to salvage the ship has brought new attention to the need to preserve the ships and keep their human passengers from being disturbed.

Early ships, especially those involved in the early exploration or exploitation of the Americas, were small by today's standards. The number of people on board was limited. The contents of the ship tend to directly reflect the ship as a sailing vessel and a conveyance of people and material. These wrecks represent a very thin slice of time and a limited range of activities—a much more compressed picture than that given by a land site. For those reasons, the proper discovery, recording, and recovery of these sites is both delicate and critical to our understanding of the past.

In the 1960s and 1970s, a movement developed to protect these sites in addition to dryland sites. Various maritime laws already pertained to shipwrecks, e.g., the Law of Salvage and the Law of Finds. However, these laws were more focused on who had rights to the material found on a wreck. The purpose of these laws was not conservation or care of the wreck. Moreover, establishing the exact location of a wreck is important in determining if the wreck comes under specific national or state laws, international laws of the high seas, or international conventions. The U.S. Park Service has created a number of National Marine Sanctuaries to protect underwater cultural sites, such as shipwrecks. The Abandoned Shipwreck Act of 1987 vested the states with the authority to manage abandoned historic shipwrecks. In 2001, the Convention on the Protection of the Underwater Cultural Heritage was

adopted by UNESCO to provide uniform definitions and protections for underwater sites. http://www.indiana.edu/~arch/saa/matrix/acl/acl_mod12.htm (accessed August 2008).

In 1985, Mel Fisher and his team found a ship from the Spanish treasure fleet of 1622, *La Nuestra Señora de Atocha*, or, just the *Atocha*, and the *Santa Margarita* (Fig. 5). Both ships sank in a violent storm with all hands on board and a fortune in gold, silver, and emeralds. Fisher's finding of the ships sparked a controversy about who owned the riches, and who had the rights to salvage the riches. In archaeological circles, the controversy also centered on the role of private excavations, or excavations for profit, versus scientific investigation. It is certainly true that much important historic research was conducted on these two important ships. Not only was there gold and silver, but also there were navigation instruments, military arms and swords, personal items, and many, many bones. Some of the objects had been made by new world craftsmen but under Spanish direction—some of these items are unique. The analysis of the animal bones told a fascinating picture of life on board an overcrowded ship of the time. However, regardless of the historic and scientific potential and actual work done, it is the wealth of the *Atocha* that continues to capture the imagination of the public.

Finding the *Atocha* sparked the search for many other sunken treasure ships. The legal arguments resulting from the private recovery of the *Atocha* still have impact today and continue to be tested.

The sinking of the *Sultana* offers another fascinating example of an underwater wreck. However, unlike an oceangoing treasure ship, the *Sultana* was a steamship full of people and commercial goods steaming up the Mississippi River toward St. Louis. On April 27, 1865, the ship exploded and burned. More than 1,500 people were killed, many of them Union POWs recently released from a Confederate prison. The ship sank and eventually its original

Fig. 5 Beautiful artifacts recovered from the *Atocha* spark the imagination but tell only a small portion of the story represented by the shipwreck.

location was lost because the channel of the Mississippi River itself moved. The sunken ship became entombed in earth. Both the *Atocha* and *Sultana* are important shipwrecks that reveal important historical incidents. Both were recovered using many appropriate archaeological techniques and both drew upon the services of professionals and nonprofessional alike. However, the presence of great wealth on the *Atocha* will forever overshadow its historical importance while the *Sultana* will be remembered for the tragic event that caused its sinking.

The Sunken Military Craft Act H.R. 4200 was passed as part of the Ronald W. Reagan National Defense Authorization Act for Fiscal Year 2005.

The House bill contained several provisions (sec. 1021–1028) that would protect sunken U.S. military vessels, aircraft, and spacecraft, as well as the remains and personal effects of their crews from salvage, recovery, or other disturbance without authorization from the secretary of the military department concerned. These provisions would clarify the circumstances under which such sunken craft, entitled to sovereign immunity when they sank, remain the property of the flag state until officially abandoned. They would also encourage the negotiation of international agreements to protect sunken military craft. Finally, the provisions would authorize the secretary of the military department concerned to issue and enforce permits for activities directed at sunken U.S. military craft, including contract salvage. This system would not invalidate any permitting system currently in place nor affect any prior lawful transfer or express abandonment of title to any sunken military craft. The Senate amendment contained no similar provision. The Senate recedes with an amendment that would authorize the Secretary of the Navy, in consultation with the Secretary of State, to apply the permitting system established by these provisions to any foreign sunken military craft located in United States waters, if requested by the flag state of that craft. It would also authorize in rem liability against a vessel involved in a violation of these provisions, and would authorize the Secretary concerned to request the Attorney General to seek other relief in certain cases. It would establish an eight-year statute of limitations for actions to enforce violations of these provisions or any permit issued thereunder. It would also extend the prohibition on applying the law of finds to sunken military craft to foreign craft located in U.S. waters. Finally, it makes technical changes to the definitional section. <http://www.history.navy.mil/branches/org12-12b.htm> (accessed August 2008)

SITE PRESERVATION IN AN INCREASINGLY CROWDED WORLD

All of these laws recognize that the “site” has the most historic value and integrity when the human-made structure is left on its original location. The laws also recognize the problem of looting of sites for monetary and personal gain. Looting of artifacts for profit is a very old activity

but one that is still vigorous today. Yet, the world does not stand still; the locations of many historical and archaeological sites, per se, make them vulnerable. Archaeological and historic house sites increasingly draw the attention of real estate developers as they try to satisfy the needs of our expanding human population. Perhaps an archaeological site along a river was isolated or an historic farm might have been miles from the nearest town when it was built a 100 or 200 years ago. Today, those same sites may well be in the city or targeted for housing development.

When such sites are endangered, the options are few and rarely ideal from the standpoint of historic preservation. Of course, the best option for the historic structure is to preserve it on its original site and require that any development bypass the site. If the site is of sufficient historical importance and if there is an active preservation community to advocate for preservation, then the site can be saved. Other outcomes are more likely, however.

Sometimes, historic structures are moved from their original sites. While not the best solution from an historical perspective, this solution may put an historic building on a site that can be preserved through time. The Conner Prairie historical site near Indianapolis, Indiana, is an excellent example (Fig. 6). In decades past, architectural and historically significant buildings were moved from their original sites to one expansive private property owned by the philanthropist, Eli Lilly. The buildings were variously conserved and renovated depending on their conditions. Today, Conner Prairie offers a wide variety of excellent living history programs that utilize the period buildings on the site. It is a popular destination for families to not only see a glimpse of the past through the buildings, their contents and interpreters, but also to participate in a wide range of programs for all ages of visitors.

An example of how an historical house can be saved and moved is the Isaac Cody house, built in 1841 in LeClaire, Iowa. Isaac was the father of William F. Cody, later to become known as Buffalo Bill (Fig. 7). In 1933,

Fig. 6 Conner Prairie, near Indianapolis, uses buildings, objects, activities, and in-character presenters to bring the past alive.

Fig. 7 Buffalo Bill's Boyhood Home is an example of an historic structure that has been saved although it has been moved; in this case from Iowa to Wyoming.

Cody's boyhood home was obtained by the Chicago, Burlington & Quincy Railroad Company and moved to its station in Cody, Wyoming. The boyhood home served as a tourist attraction in the town founded by Buffalo Bill in 1896. By 1948, railroad business was rapidly diminishing as a result of the rise of the private automobile. The railroad company donated the 106-years-old house to the Buffalo Bill Memorial Association which placed it on the site of the original museum near downtown Cody, Wyoming. In 1969, the Buffalo Bill Museum moved across Sheridan Avenue to a new museum facility and more expansive space. The boyhood home moved, too. In 2004, the house was moved a fourth time to its present location within the Greever Garden of the Buffalo Bill Historical Center. With each move, the house was thought to be important enough to protect, but as circumstances and ownership changed, so too did the location of the house itself. Hopefully, the house's roaming days are over.

Archaeological sites face other pressures. In North America and much of the world, archaeological sites are not remnants of stone, adobe, or wooden structures that stand above the ground. Rather they are beneath the ground's surface. For that reason, they are difficult to see and sometimes hard to find. Determining the actual physical land area and significance of such sites is often difficult. Archaeological sites, small and large, have been destroyed by the thousands over the last century through expanding mechanized agriculture. Destruction was not the intent of the farmer who tries to make a living and feed the world, but the impact of using larger equipment, deep plowing equipment, and terracing practices to reduce erosion have had negative effects on sites. Making the situation worse, many archeological sites were created by their original inhabitants along the nation's rivers and major streams. These areas provided the richest resources for ancient people who depended on hunting, gathering, and early agriculture to support ancient cultures. Unfortunately, those same rich river valleys are the places that

Euro-American farmers chose for their farms, too. Modern farming and river towns often were built on ancient sites.

Today, states have continuing archaeological survey programs that document sites as they are found. Many historic preservation officers actively work with local farmers, ranchers, and avocational archaeological groups to identify sites and preserve them. The Archaeological Conservancy, founded in 1980, is a national nonprofit organization that seeks to identify threatened sites and provide economic incentives to the owners to preserve such sites. *American Archaeology* is a magazine published by the Conservancy to highlight important sites, research, and issues related to America's prehistoric past. Destruction of archaeological sites is still a problem, but today, there are many more active individuals and organizations who work to save this dwindling resource for future generations.

THE IMPACT OF TOURISM

Historical tourism has been a major factor in preserving many sites and important structures, but it is also a double-edged sword. Increased tourism generates considerable money that can be used for preservation and interpretation of important places. Tourism brings much needed public attention to important sites and provides an economic incentive to local businesses to preserve the resource. At the same time, the increase in foot traffic degrades the site. Increasing tourism has spawned a variety of approaches to presenting the past. In decades past, there were numerous archaeological sites, often burial sites, which exposed ancient human remains and their accoutrement of grave goods, for the benefit of fee-paying visitors. In the late 1960s, some American Indian groups began to object to what they saw as sacrilegious exploitation and cultural commodification of their ancestors for profit.

Initially, mutual distrust was common among the various constituencies. At Dickson Mounds, near Lewistown, Illinois, many local residents believed that Indian people from other parts of the country were unfairly maligning Dickson Mounds and the local people themselves. With picketing, intervention of the Governor, and hard feelings on all sides, Dickson became a flashpoint of controversy. However, out of this conflict have come new sensitivities and new approaches to presenting the past. Dickson Mounds, a branch of the Illinois State Museum, has been a leader in this effort. Today, the skeletons of the ancient dead are no longer on view, but there are excellent life-sized dioramas that depict aspects of past cultures that lived along the Illinois River. In addition to the fine museum exhibits, there are a wide range of living history activities for visitors related to practices of agriculture, tool making, and house construction developed by Indian peoples over thousands of years. Temporary exhibits show that Euro-American inhabitants of the valley farmed,

fished, hunted, and collected in the valley and on the river for the same purposes as did generations of Indian peoples millennia earlier.

Other kinds of archaeological sites also have become historical attractions. One of the most common methods for hunting buffalo on the vast American and Canadian Plains was the buffalo jump. In its simplest terms, Indian cultures of the last 10,000 years periodically drove herds of buffalo, sometimes small numbers of animals and sometimes large, over a cliff. Those animals that were not killed by the fall or crushed by the bodies of other buffalo falling on top of them, were killed with lance, club, or arrow. The Head-Smashed-In site, near Fort Macleod, Alberta, Canada and the Vore site, just off Interstate Highway 90 on the southern edge of the Black Hills in Wyoming are examples. Head-Smashed-In offers many programs for the casual visitor to learn more about buffalo jumps and the Indian people who used them. Equally important, the site continues to be an important cultural site to the Blackfeet people.

Mammoth Cave in Kentucky offers yet another unusual type of site. As the name implies, it is a massive natural complex that offers an extraordinary view of underground geology, flora, and fauna. The cave also was used by Indian people to mine minerals. In the eighteenth century, Euro-Americans mined other kinds of minerals in the cave. Truly, Mammoth Cave provides an immersion experience.

MUSEUM EXHIBITS AND LIVING HISTORY SITES

The philosophy of presenting the past to today's visitors may be described as two dichotomies; the museum exhibit versus living history, and description versus interpretation. The "museum exhibit" perspective often provides displays, dioramas, or other constructed means of showing a past event or activity. For the visitor, the experience is usually passive and the methods of communicating the museum's messages are primarily visual and auditory. In contrast, a "living history" approach uses real people wearing period clothing and using period objects to engage the visitor in the experience of an earlier time. Here, the visitor may be immersed in the past and the interpretive messages may impact all the senses. In simplest terms, there is learning by seeing and learning by

doing. Most really good site museums will use many different ways to engage the visitor. Museum interpreters recognize that people learn in a variety of ways and therefore the messages should also be delivered through a variety of methods in order to be effective.

The second dichotomy, description versus interpretation, also underlies presentations at historical and archaeological site museums. Description and interpretation are not independent or mutually exclusive. Perhaps they should be thought of as different points on the same scale. Description tells the visitor what he or she is seeing. The farther one goes back in time or the more distant from today's urban, virtual life, the less likely it is that visitors are able to intuitively determine what they are seeing. Description may tell a person that the object in front of them is a stone-tipped spear point, fastened to a wooden shaft. Naming the type of stone or wood involved may give the viewer additional appreciation of the objects. Interpretation provides a context for the objects on view and helps answer the questions, "Who made this?" and "How was it used?" Interpretation has the power to use a single object to reconstruct an entire culture. Using the stone-tipped spear point as an example, interpretation leads to reconstruction of how the raw material was found, shaped into a tool, and then used. Behind the object, the person who made or used it is revealed. Was the tool made by a man or woman, an aged craftsman, a young hunter, or a child learning the process? From the reconstruction of the event in time, interpretation leads the audience to questions about the society in which the people lived.

CONCLUSION

Historic and archaeological sites are connections to our past. They offer incredible opportunities to not only see, but to vicariously experience what it must have been like to live in another time. Such sites also are like endangered species. They are few in number and under considerable pressure because of the land upon which they occupy. Many individuals and organizations have worked to create laws to protect the most important of these sites. When such sites are managed and interpreted by professional staffs, the site is more likely to be saved. A well interpreted site also is likely to be of greater appeal to audiences who help support the site, and thereby, help preserve it.

Historical Societies

Mark Sgambettera

Bronx County Historical Society, Bronx, New York, U.S.A.

Abstract

The central mission of historical societies, to collect and preserve the records of the past, has remained consistent over the course of the last two centuries, but the scope and the functions associated with these original objectives have changed markedly. This entry will look at some of the major historical developments that shaped the goals of historical societies, while highlighting some of the institutional transformations among historical societies that resulted from new ways of thinking about the collection, preservation, and dissemination of historical records.

INTRODUCTION

Modern historical societies are a product of the developing nation-state. Their development follows the course of public interest in collecting, preserving, and publishing documents of the founding and pioneering generations, indigenous cultures, and natural history. By the turn of the twentieth century, historical societies were adopting professional standards of scholarship and librarianship then being articulated through advanced degree programs and the publication of referenced and peer-reviewed articles and books. At mid-century, many historical societies began to adapt their missions and provide funding in support of public programs. Over the last half-century, historical societies have recognized the need to actively engage a public audience and present historical content through history education and museum programming. Computer technology has enhanced the ability of historical societies to deliver digital content including images, text, and music, anywhere in the world. Currently, historical societies are collaborating with partners from other academic and cultural heritage institutions, as well as professionals in the fields of education and information technology to create digital content that is accessible on the Internet and the World Wide Web. In fulfilling the mission of historical societies to collect, preserve, and provide access to historical records, librarians and archivists will increasingly rely on computer technology such as digital scanners, Web design tools, e-mail, and chat programs to develop and manage their unique collections and provide reference services.

HISTORICAL SOCIETIES TODAY: ORGANIZATION AND MISSION

Historical societies collect, preserve, and provide access to printed records and material culture of enduring value

related to a particular place, people, way of life, or event. Historical societies are typically structured as state-chartered, nonprofit corporations that operate as private and independent institutions or as quasi public-private institutions that receive financial aid from state and local governments. Historical societies define their mission statement, their area of interest, and their goals in a founding charter document; periodically, a society reviews and updates specific policies such as its collections policy. For example, the Georgia Historical Society (GHS), a private, nonprofit corporation chartered by the Georgia General Assembly in 1839, upholds the institutional mission “to collect, preserve, and share Georgia history through a variety of exciting educational outreach programs and research services.” More specifically, the GHS collection policy describes its primary areas of interest in terms of geographical boundaries, chronology, and historical themes, including Georgia and Georgians, the original 13 colonies, and immigration to the state. The GHS manages its collections through the processes of acquiring, accessioning, and deaccessioning historical records. Within the bounds of its legal authority, and its technological and financial resources, the GHS builds its collections by acquiring materials through purchase, donation, and deposit. Once records are acquired, librarians or archivists accession the materials into a library catalog or an archival listing, and devote all necessary and available resources to preserve the entire collection. However the GHS also reserves the right to deaccession, or dispose of, previously acquired materials that are no longer considered suitable for its collections.^[1]

While the central mission of historical societies to collect and preserve the records of the past has remained consistent over the course of last two centuries, the scope and the functions associated with these original objectives have changed markedly. This entry will look at some of the major historical developments that shaped the goals of historical societies, while highlighting some of the

institutional transformations in historical societies that resulted from new ways of thinking about the collection, preservation, and dissemination of historical records.

NATIONALISM AND THE RISE OF THE MODERN HISTORICAL SOCIETY

Modern historical societies are a product of the developing nation-state. Their development follows the course of public interest in collecting, preserving, and publishing documents of the founding and pioneering generations, indigenous cultures, and natural history. The first modern, independent historical societies were established in the United States during the late eighteenth and early nineteenth centuries. In the wake of the American Revolution, bibliophiles and amateur historians such as Reverend Jeremy Belknap (1744–1798) and John Pintard (1759–1844) solicited and combined print resources in private library associations for the purpose of collecting and communicating to the members of the society unpublished manuscripts, printed books and pamphlets, artifacts, and reports on “the natural and political history of America from the earliest times to the present day.”^[2] Under the stewardship of Reverend Belknap, the Massachusetts Historical Society (MHS) (1791), became the first historical association funded and operated by its members. Other independent historical societies including the New York Historical Society (NYHS) (1804) and the American Antiquarian Society (1812) took the lead in acquiring books, pamphlets, newspaper, and other records that documented the regional cultures of New England, the Mid-Atlantic, Virginia, and the Carolinas and helped to distinguish and connect the history of these societies with the larger Atlantic world. Historical societies made their records accessible to their members through the library and through the sale of published collections. Among the early publications were catalogs of materials held by the larger societies like the MHS and the NYHS.^[2]

As an expanding nation, the United States began in the 1790s to organize large western land territories into self-governing states. Emigrants, predominantly from the eastern seaboard states, settled newly constituted territories like Wisconsin (1787). One such immigrant, Lyman Copeland Draper (1815–1891), a seminarian and an avid collector of history and biography, settled in Wisconsin after living many decades in upstate New York. Lyman Draper helped promote the first state-funded historical society in Wisconsin. Draper successfully lobbied the newly constituted Wisconsin State Legislature (1848) to establish a charter for a historical society. The succeeding charter of 1853 stipulated that the state legislature would provide the State Historical Society of Wisconsin (SHSW) with annual subsidies, and that membership to the SHWS would be open to any who paid an annual fee of \$1. This aspect of the charter gave the SHSW the character of a

public subscription library, which distinguished it from the independent historical societies of the East like the MHS that provided services to a limited membership. The society’s institutional mission also spoke of the unique conditions upon which Wisconsin was founded. The charter of 1853 called upon the society “to secure from oblivion the memory of its early pioneers, and to obtain and preserve narratives of their exploits, perils and hardy adventures.”^[3] Over the course of the nineteenth century, the SHSW collections came to embody Wisconsin state and American historical consciousness, as its members sought to shape the state’s historical identity vis-à-vis the nation and the West.^[4]

The development of modern historical societies is unique to each nation, state, and locality. During the mid-nineteenth century Russia and Britain, like the United States, were rapidly expanding their continental and oceanic empires. At the same time, explorers and amateur ethnographers were documenting the lands and peoples of Asia, Africa, and the Americas. Institutions of learning such as the Geographical Society of London (1830) and the Russian Geographical Society (RGS) (1845) were established to collect, preserve, and publish ethnographic and historical records about the people who inhabited the imperial domains. The ethnography department of the RGS actually served as the first historical society of St. Petersburg. By 1866, a separate historical society was founded in the same city. The RGS charter called upon its members to “study national culture, arrange archaeological expeditions, and preserve monuments of the past.”^[5,6]

At the turn of the twentieth century, the breakup of empires around the world led to the rise of independent republican forms of government. The birth of independent republics quickly led to the development of cultural institutions that were capable of expressing national and regional identity through history. Six years after gaining independence, the Republic of Turkey established the Turkish Historical Society (1931) through the patronage of leading nationalist figure and first president of the Republic, Mustafa Kemal, Atatürk.^[7] Similarly, the creation of the Commonwealth of Australia in 1901 spurred organizing efforts among local and regional societies including the Royal Australian Historical Society (1901), the Royal Historical Society of Victoria (1909), and the Royal Historical Society of Queensland (1913).^[8]

Over the course of the nineteenth and early twentieth centuries historical societies were formed into state and local associations. These societies protected and preserved the past at a time when few other institutions were in place to assume guardianship over the founding documents of the community, state, and nation. The generations of historians, ethnographers, and genealogists who established independent and state historical societies were amateurs and enthusiasts, not trained professionals. Figures like Lyman Draper were not professionally trained historians; they pragmatically developed their skills as librarians and

archivists, genealogists and ethnologist, historians and editors. Though as the nineteenth century neared its end, a new generation of professionally trained librarians and historians assumed responsibility for collecting and preserving the past.

PROFESSIONALISM AND LIBRARIANSHIP

By the turn of the twentieth century, the practice of history and librarianship were becoming increasingly professionalized through higher education and the issuance of advanced academic degrees, and the publication of referenced and peer-reviewed articles and books. Beginning with the *Historische Zeitschrift* in Germany in 1859, historical associations published journals featuring original research, analysis, and annotated bibliographies. Journals like *Revue historique* (1876) and the *American Historical Review* (1895) provided a national forum and standards for historical scholarship while also offering university education programs scholarly publications for use in training future historians. In this professional environment, the historical society library came to be seen as a source of authentic historical records to be used by scholars and students. And the increasing scholarship would be published in an expanding array of historical society journals such as *The Pennsylvania Magazine of History and Biography* (1877) and the *Virginia Magazine of History and Biography* (1893).

Historical societies reinforced their role as centers for scholarly research by forming partnerships with state universities and archives. The SHSW was one of several publicly funded historical societies that established an institutional connection with a major research university; in 1900, the SHSW celebrated the opening of its new library on the campus of the University of Wisconsin at Madison. The Georgia Historical Society, on the other hand, established an editorial partnership with the University of Georgia in 1917 through which they published the scholarly journal *Georgia Historical Quarterly*. For some historical societies, legitimacy and institutional standing would become intimately tied to professional standards issued by and judged according to the historical academy. National associations such as the American Library Association (ALA) (1876) and the American Historical Association (AHA) (1884) reinforced professional standards through published resource guides and codes of ethics, annual conferences, and the issuance of accreditation standards.

Reuben Gold Thwaites (1853–1913) was among the generation of professionally trained historians who took an active interest in developing national standards of librarianship and historical research among societies in the United States. Thwaites served as the director of the SHSW from 1887 until his death. During his tenure at the SHSW, Thwaites edited several major historical documents series including 73 volumes of *The Jesuit Relations and Allied Documents* and 10 volumes of the *Collections*

of the *State Historical Society*. He was also instrumental in relocating the SHSW library collections to the University of Wisconsin at Madison.

As a member of the AHA and as president of the ALA (1900), Thwaites was an outspoken promoter of professional standards for state and local historical societies. In 1906, he wrote a report on behalf of the AHA entitled, “State and Local Historical Societies,” in which he laid out general professional guidelines for historical societies to follow. Thwaites urged historical societies to avoid the tendency to passively accept whatever was deposited on their doorstep and to actively collect public and private records and oral history accounts of the pioneering generations. These records, he noted, were to be cataloged and indexed so they may be located upon request.

Thwaites also presciently understood the power of public exhibitions for generating interest in history. Citing evolving standards of museum display, he suggested that historical societies cultivate public interest in history by introducing a rotating schedule of museum exhibits featuring carefully labeled books and objects, and lectures presented to teachers and students. Societies, he argued, could also reach a larger public audience by publishing original essays and primary source documents, monographs, and bibliographic guides to publications held in other state and local history centers. Not satisfied to allow historical societies to continue publishing inaccurate or poorly edited sources, Thwaites sounded a call for a more scholarly approach to historical research.^[9]

Historical societies incorporated the theories and practices of librarianship to organize and manage their growing collections. The experience of the Historical Society of Pennsylvania (HSP) demonstrates the fitful approach many historical societies adopted with regard to establishing professional standards of librarianship during the period 1890–1945. On the one hand, the HSP committed to a sustained collections preservation program. Between 1889 and 1910, the society set about renovating or constructing fireproof structures to house its collections. Over the ensuing decades, the HSP added steel bookcases and fireproof enclosures. However, during the renovation process HSP staff uncovered “thousands of documents. . . that had been allowed to languish unprocessed and uncataloged in boxes in out-of-the-way corners.”^[10] A lack of financial and human resources was surely a principal reason for the constant backlog of uncataloged materials at the HSP. However, as Sally Griffith noted in her study of the HSP, even by the 1920s, “none of the staff had received formal training.”^[10] Those employed at the HPS “took pride in holding complete knowledge of their collections in their head” and felt uncomfortable with “the new public libraries and had little interest in standardization or efficiency.”^[10]

Like many historical societies operating in the first half of the century, the HSP employed a variety of native catalog and classification schemes to organize their collections. Historical society indexes and card catalogs often

did not conform to nationally recognized standards such as Melville Dewey's decimal system, the Library of Congress's subject headings classification, or to archival arrangement and description inventories developed by the National Archives. It was enough for historical society librarians to know how to locate items requested by its patrons.

In the 1930s, under the guidance of head librarian Julian Boyd, the HSP revised its collections management program. Boyd sought to improve and monitor access to the society's collections through the use of circulation records and the publication of research guides, indexes, and bibliographies. Boyd recognized that he did not have enough staff to implement the ambitious program; it was difficult simply to reduce the backlog of uncataloged materials—including tens of thousands of pamphlets—let alone catalog current acquisitions. As Boyd himself learned, the mountain of uncataloged materials hid unknown treasures. While preparing a catalog of HSP materials for an exhibit to commemorate the 150th anniversary of the Constitution, Boyd uncovered the only known original copy of the document. Over the ensuing decades, HSP librarians and catalogers tried to keep pace with acquisitions, and in 1944 the manuscript department could claim some measure of satisfaction in having cataloged about 95% of its collections.^[10]

The HSP was initially slow in recognizing the advantages to be gained by using technology to improve library services. For example, during the period 1912–1930, when research institutions throughout the United States had begun to use new Photostat copying equipment to reproduce and circulate precious historical documents for use outside their own libraries, the HSP leadership steadfastly refused to give reproductions of its collections to other libraries. However, in the 1930s, as the society became increasingly aware of the extent to which other institutions were accumulating Photostat collections for use as reference and research materials, they adopted new policies that allowed for the photocopying and circulating of materials held in the HSP collections. Whereas the HSP was initially hesitant to adopt Photostat technology, under Boyd's tenure, the HSP adopted the use of microphotography as a method to copy and preserve its own collections and gain permanent access to original materials held by institutions.^[10]

Though historical societies were adopting professional standards of scholarship and librarianship during the first half of the twentieth century, most societies were providing library services for a limited clientele. Primarily, historical societies opened their doors to the ranks of historians and librarians; some of these professionals went on to staff historical society libraries, while others made use of historical society collections to write articles for historical society journals. The HSP, for its part, opened its doors to the general public in the twentieth century; it just did not advertise this fact. The HSP leadership and

staff “did not consider it part of their purpose to try to attract a broader audience.”^[10] However, at mid-century, many historical societies began to adapt their missions in order to provide funding and staff support for programs aimed at public audiences interested in national and local history. In the process, some historical societies learned how to connect history with popular museum exhibitions and ultimately donor solicitations.

PUBLIC HISTORY AND INSTITUTIONAL GROWTH

Over the last half-century, the number of historical societies has increased markedly in absolute terms. The mission of historical societies has also expanded with the drive to actively inform citizens through history education and public programming.

Jan Partridge, in her article about cultural heritage institutions in Australia, noted that the number of local studies centers has increased significantly since the 1950s. She cites figures based on a 1999 study conducted by Alan Bundy which indicate that 76% of public libraries in Australia possess a local studies collection.^[11] Likewise, the number of historical societies operating in the United States has increased dramatically. The Conference of Historical Societies' *Handbook of American Historical Societies* published in 1926 listed 338 national, state, and local historical societies. By the mid-1980s the number of historical societies had surpassed 9000.^[12,13]

At the local level, it has often been the case that public support for historical societies follows the commemoration of significant historical events. Jan Partridge noted that the overwhelming majority of public libraries in Australia began collecting local studies materials in the 1980s, a decade that coincided with the bicentennial celebration of white settlement in Australia.^[11] Similarly, in 1987, around the time of the centennial anniversary of the founding of Boksburg, South Africa, a local resident, Connie Nelson-Esch, published an article in the *Boksburg Advertiser* about the history of the community. The article spurred other residents to organize the Boksburg Historical Association (1993) to collect and preserve the “history of the city and its people.”^[14]

Local historical societies around the world have been aided by national organizations such as the American Association for State and Local History (AASLH) (1940), the British Association for Local History (1982), and the Federation of Australian Historical Societies (1977). Since the 1940s, the AASLH has served as a clearinghouse of information for societies in the United States and Canada. The AASLH regularly publishes a *Directory* of members, as well as how-to guides on topics like *Organizing a Local Historical Society*, *The Management of Small History Museums*, and *A Guide to the Care and Administration of Manuscripts*, as well as bulletins about topics ranging from historic house renovation to public relations.^[15]

Today most historical societies offer a good deal more than a research library collection and a catalog of publications. The experience of the Virginia Historical Society (VHS) in the postwar years highlights two significant trends in the development of historical society missions. Over the last 30 years, historical societies have assumed a larger role in educating the public about their collective past. At the same time, historical societies have found it necessary to adopt corporate models of business management particularly in regard to advertising and fund raising.

In 1978, the VHS changed its executive committee structure replacing the formerly self-appointed executive committee with an elected board of trustees. With this institutional change came an incremental shift in the VHS's focus away from its traditional emphasis on developing its research collection and offering library services to a selective academic clientele. In the wake of the United States Bicentennial, the trustees of the VHS became aware of the growing commitment of universities, museums, libraries, and other historical societies to engage students, teachers, and the general public in historical conversations about the nation, freedom, diversity, and unity.^[16] In particular, scholarly debate and public discussion embraced a new social history of underrepresented historical figures. Indigenous populations, minorities, and women, and broad social movements for labor and civil rights found expression in public exhibitions, lectures, and education programs.

The VHS began offering its first public museum exhibits in 1987. It would later add theme exhibits such as the Jewish experience in Virginia, racism, and labor. Along with museum exhibits, the VHS took active steps to help shape history education curriculum for teachers and deliver new historical materials to students. The VHS initiated an education program under a separate department in the mid-1990s. Among the many programs initially sponsored by the education department of the VHS were school tours of the museum and library, docent training for volunteer staff, the writing of educational primers for teachers, and guest lectures at affiliated educational institutions. By the mid 1990s, the VHS's mission statement included a research library, a museum and historic houses, traveling exhibits, lectures, and programs, training and services for students, educators, and other local history societies, book and periodical publications, fellowship programs, and collaborative archival projects. With the wealth of public programming being made available, the question became how to pay for it all.^[17]

For the VHS, the postwar years were years of growth: by the mid-1970s, the VHS added over 6.5 million processed manuscript items, while the photographic and print collections doubled in size. For most historical societies, meeting the demands of an expanding collection, an aging building, and technology upgrades required the infusion of millions of dollars. In an era of shrinking federal and state budgets, this could only come from private and corporate donors. The VHS undertook its first

large-scale donor solicitation program in the late 1980s with the Center for Virginia History and the Fifth Century Campaign to raise \$12 million for capital construction. In order to reach its goal, the VHS had to sell itself to the public, and this required publicity. The VHS established a publicity office in 1988 and a development office soon thereafter. The society opened its first corporate-sponsored public event in 1989, an exhibit of the society's premier object collection. Over the next two decades, the VHS solicited close to \$100 million with much of the proceeds earmarked for the support of public programming such as a new 10,000 sq. exhibit hall. By the late 1990s, the VHS maintained a permanent museum exhibition, and offered 8–10 temporary installations per year, while drawing an average of over 20,000 visitors annually.^[17]

HISTORICAL SOCIETY AS DIGITAL LIBRARY

Historical societies are currently collaborating with partners from other academic and cultural heritage institutions, as well as professionals in the fields of education and information technology to create digital content that is accessible on the Internet and the World Wide Web. Historical societies are making use of digital scanners and camera equipment to capture images of text documents, photographs, and objects that can be easily stored in multiple file formats and integrated into an online public access catalog. The introduction of lower-cost, user-friendly digital capturing, storage, retrieval, and networking technologies, along with the development of nationally recognized standards for digital cataloging and description metadata has greatly enhanced the means through which small and medium-sized historical societies can preserve and provide access to their unique collections such as phone directories, loose sheet maps, or post cards.

Over the course of the last decade, historical societies have developed digital libraries as a means to reach out to larger communities of users and provide a nexus for collaboration between scholars, students, teachers, and amateur historians. State and local repositories including historical societies are establishing digital consortia to facilitate cooperative collecting of historical records that document a particular social theme, historical era, or ethnic group. These cooperative collections emphasize the institutional strengths of individual historical societies and support the needs of educators, researchers, and students. The Oregon Historical Society (OHS), for example, has joined with Washington State University and the state historical societies of Idaho and Washington to create a tristate Columbia River Basin Ethnic History Archive (CRBEHA). The goal of the project “was to identify, digitize, and describe library and museum collections concerning non-Native American ethnic groups of the Columbia River Basin, and to stimulate public use of and

discussion of those sources.” Principally, the CREBHA project allowed the OHS to pursue its mission to raise public awareness about its collections and develop educational resources.^[19] In this regard, the OHS was able to provide public access to some of its vast collection of photographs and family papers.

The Web portal developed by the CREBHA consortium offers direct access to selected historical records and novel ways of collocating records based on key word searches. The Columbia River Basin Ethnic History Archive also offers interpretive tools for users and teaching aids, and allows for the migration of content pointers and metadata from one database or catalog to another through the Open Archives Initiative-Protocol for Metadata Harvesting.^[18]

The introduction of new technologies has not significantly altered the mission of historical societies to collect, preserve, and disseminate the records and material culture of a specified place, people, way of life, or event. However, the digital library environment and electronic publishing do offer efficient and inexpensive means for historical societies to provide access to their unique collections, present rich, interactive educational content, and, perhaps most importantly, collaborate with other historical societies and cultural heritage institutions to build fully searchable, subject specific digital catalogs.

CONCLUSIONS

Historical societies will continue to provide a number of services to the public in the digital age. Historical society librarians will produce a variety of research and reference materials including bibliographies, indexes, guides to the collection, and educational materials. As with librarians more generally, society librarians will answer reference questions about local and national history, geography, current events, institutions, and personalities. However, in fulfilling the mission of historical societies to collect, preserve, and provide access to historical records, librarians and archivists will increasingly rely on computer technology such as digital scanners, Web design tools, e-mail, and chat programs to develop and manage their unique collections and provide reference services. The process of digitizing historical collections will raise many significant challenges for historical society staff, not the least of which will be acquiring skills in database design, navigating copyright law and fair use provisions in a digital environment, and securing continued funding for the preservation of digital and non-digital content. Historical societies will, however, find technological, financial, and legal support through consortia partnerships with research universities. Ultimately, the unique collections of historical societies will be widely shared for the purposes of research, public exhibitions, and educational programming.

Historical Sources and Their Users

Margaret Stieg Dalton

School of Library and Information Studies, University of Alabama, Tuscaloosa, Alabama, U.S.A.

Abstract

This entry discusses the evolution of historical study from its beginnings in the realm of mythology to the present complex world of multiple audiences, multiple approaches, and a scope that touches virtually every area of human endeavor. Paralleling this evolution of scholarship has been a constantly expanding universe of sources deemed appropriate to provide the evidence upon which historians base their assertions. The related topic of scholarly communication among historians also receives attention.

INTRODUCTION

This entry will attempt to show how the world looks from the historian's point of view. It will discuss the values and priorities of historians. It will endeavor to illuminate the relationship between the questions they pose and the sources they use, and to shed light on how both internal and external forces are changing the enterprise.

History—writing about the past, not the past itself, which is also “history”—is an endeavor, activity, and discipline of great complexity, with little unity and an internal logic that is often contradictory. It is like an old mansion with many rooms that has been periodically added to and remodeled to suit succeeding generations. Despite extensive modification, however, a basic structure remains. The business of history was and is to provide answers to two fundamental questions: what happened and why did it happen? New additions have not changed this fundamental purpose.

Answers to those questions require evidence. The evidence may be obtained from written documents, from objects, from pictures, from oral accounts, or from any other source that contains relevant information. Records created at the time the event under investigation took place are called primary sources and offer an inside view of the event; they are the heart of any research project. Sources that interpret and analyze the event are created later and are called secondary sources. The distinction between primary and secondary sources is always relative. If, for example, someone is doing a study of Irish immigration to the United States, records like ships' registers, records of the ports of departure and arrival, and letters written by the immigrants are all primary sources. Newspaper stories and other commentaries about that immigration would be secondary sources, but could themselves be primary sources for a study of popular reaction to Irish immigration. The scholarly writings of historians themselves can become primary sources, as when the views of the nationalist German historian Heinrich von Treitschke

(1834–1896) are examined in a study of the tradition of Prussian militarism.

History depends upon a sense of linear time: there is the present; there was the past; and there will be the future. Each is different from the other and the past does not repeat itself. History also depends on the presence of a belief that an understanding of the past can illuminate present realities and that the present will influence the future.

Historical scholarship and writing serve multiple purposes. The results of such scholarship increase our understanding of human nature. They can be used to glorify the achievements of a group and to strengthen a sense of group identity. They can create myths and they can debunk myths. They provide explanations for present conditions.

It is no accident that the nineteenth century, during which nationalism spread and flourished in Europe, was a period of major development of the discipline. During the nineteenth century, many of its practitioners wrote to reinforce emerging states or to advance the claims of ethnic groups to their own state; Frantisek Palacký's (1798–1876) *Dejiny národu českého v Čechách a v Moravě* (*History of the Czech Nation and Moravia*) is credited with a major role in the development of Czech national consciousness. Not only did Palacký celebrate the Bohemian past, his use of the Czech language—in the nineteenth century Austro-Hungarian Empire Czech was the language of the peasants of Bohemia—in the volumes published in 1848 and after was highly symbolic. Twentieth century historians interested themselves in additional types of groups, such as those defined by age, by sex, by ethnicity, and by social and economic characteristics.

Those who have helped make history—the events, not the writing about the past—have often written their version of what happened in pride or self-exculpation. Among the best have been the *History of the Rebellion*, a history of the English Civil War by Edward Hyde (1609–1674), advisor to Charles I and Charles II, kings of

England, the *Personal Memoirs* of U.S. Grant (1822–1885), General in Chief of the Union forces in the American Civil War, and *The Second World War*, by Winston Churchill (1874–1965), Prime Minister of Great Britain during World War II. Now, a memoir by presidents and commanding generals is almost *de rigueur*.

How history is written can be as important as what is written. Originally, historical writing was one form of literature. Not until the development of professional history in the nineteenth century did the distinction develop between history written for historians and history written for Everyman. Today, both categories of publication flourish, although they are usually quite separate. In addition to the many books published every year by scholars and intended primarily for other scholars, there are many books on historical topics published in the hope that they will sell to and be read by a general, popular audience. In the United States, historical topics of perennial popularity are the American Civil War and World War II.

THE EVOLUTION OF HISTORICAL SCHOLARSHIP: THE BEGINNING

The writing of history has its own long history. Although they are not based on historical evidence, the creation myths that are among the earliest literature to survive are attempts to explain the past. The growth of kingdoms and empires produced annals and chronicles of events; royal chronicles date from the Middle Kingdom period of Egypt (21st–18th century B.C.). Such chronicles tend to be brief recitations of facts, but they are nonetheless a form of historical writing and have their modern counterparts, such as Elizabeth Stone's *American Library Development, 1600–1899* (1977) which gives a chronology of important occasions in American library history, but no narrative establishing connections or interpretations.

The first true historians in the West are considered to be Herodotus (c. 484–after 424 B.C.), who wrote about the Greek wars with Persia, and Thucydides (c. 460/455–399 B.C.), who wrote about the wars between Athens and Sparta. In China Ssu-ma Chien (145–90 B.C.) is usually given that honor. Thucydides wrote about war and politics as did Herodotus, but Herodotus was also interested in different peoples and their cultures. Ssu-ma Chien wrote treatises on the economy of China and on the control of its rivers and canals. What distinguished the work of these historians from that of the chroniclers was that they made an effort not only to state what happened but also to explain why it did. In addition, they paid attention to the accuracy of their sources. This combination of emphasis on sources and interpretation of the information they provide has remained a constant of historical writing through the centuries. As Sir Charles Oman wrote in 1939, "History, then, is the investigation of evidence, written or

sometimes unwritten, about series of events concerning which we are able to make some conclusion."^[1]

Historians of the late classical period and the Middle Ages carried on and expanded the genre. Sallust (86–34 B.C.) attempted to make connections between events; he portrayed the rivalry between the Roman generals Marius and Sulla to dramatic effect. Both the Venerable Bede (c. 672/673–785), an English monk, and Einhard (c. 775–840), a German monk, wrote biographies, Bede of the abbots of Wearmouth and Jarrow, Einhard of Charlemagne. In the Islamic world, Ibn al-Athir (1160–1233) produced annals of world history; Ibn Khaldun (1332–1406) constructed a model of dynastic rise and decline in his history of the Arab and Berber dynasties of North Africa. In the writings of these periods one can find examples of persisting features of historical scholarship, such as attention to sources. The Roman historian Tacitus, for example, is known to have used the official records of the Roman state, both the minutes of the Senate and the collection of the acts of the government. Bede used both documentary and oral sources. Writing about events that the historian has participated in, such as the *Anabasis* of Xenophon (431–355 B.C.), is another continuing feature of historical writing, as is the effort to obtain rewards, exemplified by Froissart (c. 1337–1405), the chronicler of the Hundred Years' War, who modified the editions of his *Chronicles* to appeal to his successive patrons.

THE EVOLUTION OF HISTORICAL SCHOLARSHIP: THE RENAISSANCE AND ENLIGHTENMENT

A shift to greater emphasis on interpretation and historical causation can be observed in the histories written during the Renaissance period. Niccolò Machiavelli (1469–1527), best known as the author of *The Prince*, was the historian of the City of Florence and wrote a history of that city–state. He took the Roman historians Sallust and Livy (59 B.C.–c. 17 A.D.) as his models and sought to illuminate universal principles and general laws. The *History of Florence* can be read as a commentary on historical method.

The Enlightenment of the eighteenth century increased the emphasis on analysis and the description of change over time in historical writing. The eighteenth century also produced the man many consider the greatest historian of all time, Edward Gibbon (1737–1794), author of *The Decline and Fall of the Roman Empire*. Gibbon's approach was to combine the new "philosophic" fashion in historical writing exemplified by such men as David Hume (1711–1776), with the antiquarian tradition and its emphasis on accuracy. Gibbon is also noted for broadening the range of source materials used; his use of the critical geography of Jean Baptiste Bourguignon d'Anville (1697–1782) and the publications of the Académie des Inscriptions are only examples.

THE EVOLUTION OF HISTORICAL SCHOLARSHIP: THE NINETEENTH CENTURY

The nineteenth century brought a constellation of changes. In 1800, most historians in Europe and the United States were amateurs and probably independently wealthy. By the end of the century they were far more likely to be professionally trained university professors. During the century universities expanded both in number and in the range of subjects in which advanced study was possible. New areas of study, of which history was one, were added to curricula that had their roots in ancient Greece. Study beyond the undergraduate level offered a means of professional preparation. The growth in higher education made it possible for those with historical interests but modest means to earn a living as historians. Simultaneously, scholarly periodicals devoted to history were established, such as the *Historische Zeitschrift* in 1859, and organizations dedicated to historical scholarship were founded, such as the American Historical Association in 1884.

In much of this extension and amplification of the historical enterprise, Germany—and one man in particular—led the way. Leopold von Ranke (1795–1886) is often described as the “father” of modern historical scholarship. Responsible for the exhortation to write history “wie es eigentlich gewesen ist” (as it really was), Ranke wrote voluminously. His first major work was the *Geschichten der lateinischen und germanischen Völker* (History of the Latin and German Peoples) which appeared in 1824 and included an appendix in which he set forth a distinctive historical methodology. His last was an ambitious world history that he was working on at the time of his death. In between, came—among others—books on the Ottoman and Spanish empires in the sixteenth and seventeenth centuries, a history of the Roman papacy in the four preceding centuries, books on Germany in the time of the Reformation, and on Prussia, not to mention books on Britain and on France. His work demonstrated what would become the creed of the professional historian: intensive research, usually in records created as close to the events as possible; and interpretation of the findings, which usually meant an attempt to distinguish between significant and details.

His own scholarship, however, was only a part of Ranke’s contribution to history. Beginning in the early 1830s, Ranke trained in his seminar at the University of Berlin the first generation of professional historians, men like Georg Waitz, Theodor Mommsen, and Jakob Burckhardt. One student, Maximilian II, king of Bavaria, established an historical commission within the Bavarian Academy of Sciences. For the remainder of the century, German universities were the places to go for the best historical training. American historians who studied in Germany included George Burton Adams (1851–1925) of Yale, William Dunning (1857–1922) of Columbia, Albert Bushnell Hart (1854–1943) of Harvard, and Clarence

Alvord (1868–1928) of the University of Illinois. J. Franklin Jameson (1859–1937), longtime first editor of the *American Historical Review*, was notable as the first American historian of distinction who had not studied in Germany.

Ranke also contributed to the development of the discipline with his attempt to found a scholarly historical periodical. The *Historisch-Politische Zeitschrift* (1832–1834) was in fact more political than historical, but it attempted to provide an historical background for current political problems. A second abortive effort was the *Zeitschrift für Geschichtswissenschaft*, founded by Adolf Schmidt (1812–1887) in 1844. The void was eventually filled by the *Historische Zeitschrift*, begun in 1859 by Heinrich von Sybel (1817–1895), which continues today. Both Schmidt and von Sybel were among Ranke’s students.

THE EVOLUTION OF HISTORICAL SCHOLARSHIP: THE SPREAD OF HISTORICAL SCHOLARSHIP

By 1900, German innovations were spreading and other features were being added. In the United States, for example, the first doctoral degree in history was awarded in the 1870s. Universities and colleges had begun to establish departments of history. The American Historical Association was founded in 1884 and the *American Historical Review* in 1895. Some universities had set up presses to publish the results of scholarship; historical scholarship was prominent on their lists from the beginning. There were, of course, national variations. In England and France, the pattern was less one of addition than of modification of older forms to new purposes. In non-European countries these developments came later, but today almost every developed country or one with aspirations for development displays similar patterns.

These nineteenth century innovations, the introduction of new canons of scholarship, the development of opportunities for advanced study in history, the foundation of organizations devoted to history, and the creation of media for the dissemination of scholarship did not, however, mean the disappearance of older patterns. Individuals who were not academically trained continued to write history, books on historical topics intended for general readers continued to be published, and articles on historical topics continued to appear in general intellectual periodicals like the *North American Review* and *Atlantic Monthly*. Among examples of American historians without formal historical training who did distinguished work at this time were Francis Parkman (1823–1893), author of the classic *The Oregon Trail*, and Henry Charles Lea (1825–1909), best known for his work on European religious history. Barbara Tuchman (1912–1989), author of *The Guns of August* (1962), is a more recent example.

THE EVOLUTION OF HISTORICAL SCHOLARSHIP: DIVERSIFICATION

The development of this integrated structure of education and publication of research brought expanded opportunities. Historical scholarship increased in quantity and diversified. While the characteristic publication format of the nineteenth century was the multivolume history, the formats of the twentieth century were the scholarly monograph and, increasingly, the scholarly article. These newer formats both contributed to and were the result of the increasing specialization of the field.

Initially, specialization tended to be by geographic area. American historians began to identify themselves as historians of a region, such as the South, the Mississippi Valley, and the West. In departments of history in the United States, the number of historians specializing in various European countries, beginning with Great Britain, increased and other areas like Asia began to be represented as those areas became of interest to Americans. Topical specialization followed; economic history and social history were added to traditional political history. In 2007, the history department of the University of California, Berkeley, a major research university and leader in doctoral study in history, had faculty who identified their specialties as Reformation Germany, comparative civil rights, women in Mexico, the history of biology, the history of crime in the United States, Chinese popular culture, and African health and gender.

Periodicals reflect this trend toward specialization. There are journals to match each of the specializations named in the Berkeley history department, journals of women's history, journals of religious history, journals of German history, journals of African-American and African history, even a journal of criminal justice history, and a journal of the history of biology. Specialization in periodicals has progressed to the point where some journals are doubly specialized, such as the *Journal of African Economic History*. There are also journals that are specialized by what one might call outlook, such as the *History Workshop Journal*, which was founded on the premise that history was a collaborative enterprise involving all interested parties. And there are interdisciplinary journals in which history is an element. When writing an article, the historian must decide which journal is the journal in which he or she would like to have the article published. That choice will affect emphases of presentation and can influence the research process to a certain extent.

University presses, the primary publishers of book length historical scholarship, also show some specialization, but theirs is more limited, since their mission is the much broader one of the advancement of scholarship rather than the advancement of one particular piece of it. A press may have a series in an area as the University of California Press does in the History of the American Cinema. Alternatively, it may lack a named series but still

have a recognized interest in an area as the University of Alabama Press does in Alabama history and the University of Notre Dame Press does in Roman Catholic history. In recent years, pressures on university presses to emphasize sales potential have forced many to publish more books on American history, for example, than on European history, as well as more non-scholarly books.

THE EMERGENCE OF THEORY

Another differentiating feature of historical scholarship that has developed in the last century and a half is that of theory. Theory in history is not the same as theory in the natural sciences, although it shares some of the same properties. In the natural sciences, theories are usually the result of experimental research. They are an explanation for a set of data or a model that can be tested by experiment. In history, theories are not subject to testing. They offer explanations, but have more in common with the older and more amorphous concept of world view or *Weltanschauung* than they do with scientific theories. They function as an approach or an intellectual framework rather than a true theory. According to John Tosh, theories in history arise because of the difficulty of understanding the interrelatedness of all aspects of human experience at a given time and because of the nature of historical change and lack of change. A theory may also attempt to provide an explanation of the overall direction of historical events.^[2]

Although historical theories have been particularly prominent in the late twentieth century, theory has been part of historical scholarship since Ranke. Until the end of the nineteenth century, the dominant principles of historical scholarship were those of historicism, a creed shaped by Ranke and his students. Historicism (Ger. *Historismus*) was, in fact, so closely identified with historical scholarship that for a longtime historical scholarship was defined by it. It emphasized the importance of close research in historical sources and the centrality of the state and political events and, by extension, defined what constituted proper subjects for historical inquiry. In contrast to Hegel's dialectic theory of history, Ranke's view was that each event is unique and an outgrowth of particular local conditions.

Not until late in the nineteenth century was there a serious challenge to historicism, a challenge usually associated with the name of Karl Lamprecht (1856–1915). Lamprecht criticized both historicism's emphasis on the state and its emphasis on political events. He urged more attention to economic and social issues, and—influenced by the newly emerging area of psychology—can be considered an early proponent of the study of *mentalités*, a concept used to describe the collective attitudes of a group. Stifled by the German historical establishment, Lamprecht's influence in Germany was largely outside

the universities and limited to regional and local history. Outside of Germany, however, his ideas were much more favorably received, as in France and the United States.

However novel his ideas about what should be studied, Lamprecht did not challenge the fundamental principle of close attention to sources. Like Ranke, he used archival collections, but where Ranke sought information relative to political developments, Lamprecht sought information relevant to social and economic developments. Ranke used repositories like the Archives nationales in Paris, the Public Record Office in London, the Central State Archives of Moscow, the Vatican, and the Venetian State Archives, Lamprecht used ecclesiastical and city archives in the Rhineland, as well as manuscript collections in libraries and private hands. Ranke's evidence might come from the reports of the Venetian ambassadors, Lamprecht's from manorial records, but the appropriateness of a particular document depended upon the questions asked rather than the form.

In contrast to the relative stability of outlook of nineteenth century historical scholarship, the twentieth century saw a succession of "theories," each one attracting a share of attention and adherents, only to be joined by yet another that attracted its own attention and adherents. The most influential of these multitudinous approaches have been those of the Annales School, the Marxist historians, the historians who have devoted themselves to the study of a particular, hitherto ignored group such as women, and the postmodernists. No single outlook succeeded in vanquishing all others or achieving dominance and the pattern has been one of addition rather than replacement. For the individual historian, these theories have not necessarily been mutually exclusive. It has been entirely possible for a historian to be simultaneously a feminist historian and a Marxist historian; the founders of the Annales group were Marxists. In the twenty-first century, enthusiasm for such intellectual structures seems to be decreasing, as Lynn Hunt, a former president of the American Historical Association, suggested in one of her columns, "Where Have All the Theories Gone?"^[3] Historians of different persuasions, however, continue to write history that is influenced by one or another outlook, even if the theoretical controversies are less strident.

The most robust of the various theoretical offerings has probably been that of the Annales group. Named for the journal founded in 1929 by Marc Bloch (1886–1944) and Lucien Febvre (1878–1956), the Annales School was characterized by openness, openness to new methods, and openness to new objects of study. Their guiding principle was that of total history (*histoire totale*); another concept identified with them is that of *mentalités*. One important member of the group, Fernand Braudel (1902–1985), contributed a unique approach to time, conceiving historical phenomena as having three periods: the *longue durée*, a period of long, centuries-long, stability in human experience, determined by such factors as climate and modes of

production, the *moyenne durée*, a period of a major trend, particularly economic cycles, and the *courte durée*, a period of a brief phenomenon like a political movement, not lingering enough to be a trend. The breadth of what was considered appropriate for study is reflected in the various names of the *Annales*, one of the more recent of which was *Annales: Économies, Sociétés, Civilisations*. Braudel's book, *The Mediterranean and the Mediterranean World in the Time of Philip II*, (orig. Fr. ed., 1966) epitomizes this breadth, both temporally and in terms of subjects, as well as by the author's attention to the writing of historians from the entire region, not only those of Western Europe. The Annales group also looked to the developing social sciences for methods and insights, early leaders in what would become a common practice.

Marxist history asserts the primacy of economic, rather than political or cultural factors, as "the engine of history." Marx's concepts of class, capitalism, and production are used to interpret events. How these ideas should be applied in historical scholarship has been the subject of debate, and individual Marxist historians have increasingly added additional components to their thinking. They have tended to interest themselves in economic history or in social and cultural matters relating to the lower classes. Frequently cited examples of works by English-speaking Marxist historians are E.P. Thompson's, *The Making of the English Working Class* (1963) and E.J. Hobsbawm's *The Age of Revolution: Europe, 1789–1848* (1962) and *The Age of Capital, 1848–1875* (1975).

Other important approaches have come from historians of gender and historians of other disadvantaged groups. These groups have found new questions to ask, new sources from which to obtain evidence, and new ways to examine previously examined events. Often inspired by personal activism, they have revealed their subjects as actors, not passive objects, and full participants in the creation of the present world. Joan Scott is a prominent gender historian.

One of the most recent schools of thought is that of postmodernism, a complicated constellation of ideas drawn from philosophy, linguistic theories, and textual criticism. In the nineteenth century, historians tended to be positivists, to believe that the past was knowable. Historical knowledge was achieved using the historian's version of the scientific method, immersion in the sources, and generalization from the evidence obtained. Historians assumed that others who used the same sources and the same techniques would come to similar conclusions. In contrast, postmodernism casts doubt on the possibility of a shared understanding of the past, a view reinforced by radical relativism's position that absolute truth does not exist. Instead, understanding depends on the reader's cultural and ideological context and, by virtue of living in another time, the historian can never share the cultural and ideological context of the document. At most, the scholar can situate a text within different discourses. Pushed to its

extreme, this position questions the possibility of historical knowledge. On the positive side, it has strengthened interest in cultural history.

These approaches hardly exhaust the varieties of approaches to historical scholarship. Some types, such as quantitative history, are more methodological practices than anything else, offering useful approaches for historians of vastly different interests. Historians, especially economic historians, have long concerned themselves with numbers, but perhaps influenced by the use of statistics in the social sciences, the use of numbers in history has considerably increased in recent years, an expansion facilitated by the development of computers. Quantitative techniques can be applied to a variety of situations; R.W. Fogel (1926–) worked on subjects as diverse as railroads, slavery, and hunger and premature death in modern populations. Other approaches draw on insights from fields outside history, like anthropology and sociology.

THE SOURCES

The character of the primary sources used by scholars in the twentieth century shows somewhat more variety than those of the nineteenth century, but overall there is a remarkable stability. The references in the articles of the first volume of the *American Historical Review* (1895–1896), a journal that has great prestige and includes history of all times, places and subjects, were compared with those in its 111th volume (2006). In both volumes, the primary materials used by the authors were almost exclusively manuscript records or printed primary material. Exceptions in the 2006 volume were a Web site that provided documentary evidence (a speech by the Tony Blair, British Prime Minister from 1997 to 2007) in one article and photographs that were a significant source of information in another article. An exception in the 1895/1896 volume was an interview in which the author of the article on the Underground Railroad had spoken with “an intelligent colored man—a barber, J.J. Minor by name,” who had been an agent on the Railroad.^[4] The citations to secondary sources in the two volumes, on the other hand, are quite different. In the 2006 volume there are abundant references to the monographs and articles of other scholars. There are virtually no citations to any kind of secondary material in the 1895/1896 volume. That difference reflects the paucity of historical scholarship in the late nineteenth century and its abundance in the early twenty-first.

History has been and continues to be largely identified with written records, but in the twentieth century the definition of appropriate source has expanded to include many kinds of non-written records. The desire to explore the history of peoples who have not left written records behind or who appear only in the written records of others inspired creativity. A particularly good example of this

new inclusiveness is recent scholarship on African history. Jan Vansina (1929–), a Belgian who after training in medieval history was appointed a researcher in anthropology in the Belgian Congo, pioneered the use of oral sources. Growth in types of sources used to write African history has progressed to the point where evidence not only from oral sources is used but also evidence from linguistic, botanical, biological, archaeological, and artistic sources.^[5] Nor is it only in less well documented fields that such alternative sources are used. Historians in general, impressed by what anthropology and sociology have achieved, show growing interest in their methods and sources of information.

A new project in history can begin in different ways: either a historian finds a question intriguing and decides to investigate it or a historian finds a collection of materials that promises to answer questions about an interesting topic. That collection may be newly discovered, as were the records of Cahokia, the first French settlement in Illinois to survive for any length of time, that were found by Clarence Alvord (1868–1928), or it may be a collection that has used by previous historians, but not used in the way the newcomer envisions. For the historian who begins with a question, the next step is the location of appropriate sources; for the historian who begins with the collection, the next step is immersion in the source.

How does a historian who begins with a question locate appropriate sources? The answer depends on what kind of sources are sought. Primary sources can be identified by the use of guides to archives and special collections, many of which are now available online, bibliographies of manuscripts, and in the bibliographies of scholars who have written on closely related topics. Conversations with knowledgeable archivists can be invaluable. Some primary sources are printed, either transcriptions of manuscript records, like the *Monumenta Germaniae Historica*, the great series of sources for German history begun by the Prussian statesman Freiherr vom und zu Stein (1757–1831) in 1819 or because the evidence the historian seeks originally appeared in a book, pamphlet, or government document.

For a book on public libraries in Nazi Germany material was located through guides to German archives, through inquiries directed to every provincial and city archives, through inquiries to existing provincial library administrations, and through inquiries to larger libraries about their own records. Printed reports of contemporary library agencies were identified through the German national bibliography. Librarians contacted frequently identified surviving librarians of the period who might be willing to be interviewed; one librarian had an important document in his possession. Secondary material was found through bibliographies and indexes and in books and articles on related topics by other scholars. Imagination, an eye for clues, and persistence are all essential. For that book on public libraries in Nazi Germany, the mention of

a 1931 attack on the collection of the public library in Rostock in a document in one repository led the historian to write to the Rostock Public Library, which forwarded the query to the university librarian in Rostock, who had done research on the episode and graciously shared his results.

The importance of archives and manuscript collections to the historian cannot be overstated, although for some topics, particularly those where quantitative methods are used, the same statement could be made about published sources like censuses, statistical reports, etc. Fortunately for the historian, governments, religious bodies, organizations, and other enterprises need to know what their actions and decisions were. Archives, defined as either a collection of records and historical documents or the place in which they are collected, date back to the ancient classical world.^[6] For the most part, however, institutions that store and service records are a modern creation. With the exception of the Papacy, heir to the Roman Empire, political entities in Europe did not begin to make formal, centralized arrangements to regulate the preservation of their records until the late eighteenth century. The Archives Nationales of France was created in 1790, the Public Record Office of Great Britain followed in 1838. The National Archives of the United States was finally established in 1934.

Public access to archives followed. After an 1851 petition signed by 83 individuals, including Charles Dickens, Thomas Babington Macaulay, and Thomas Carlyle, the right of access to the Public Record Office for scholarly purposes was granted. By early in the twentieth century, however, the interests of scholars in archives were generally acknowledged, and American historians were among the interest groups that pushed for the National Archives.

Not all records, of course, are open for to the public for use. Some government records may be closed for security reasons or what one might call pseudo-security reasons, such as the attempts of the second Bush presidency to reclassify unclassified documents to protect its actions and policies from scrutiny. Privacy concerns affect access; stringent laws have been passed in some countries to protect the privacy of individuals. Nongovernmental records, such as the records of organizations and businesses and the papers of individuals, are private property and may remain in the custody of the organizations and individuals that created them or of their heirs and successors; they may not have been opened to scholars.

Limitations imposed by inefficiency, bureaucratic indifference, and design also impede historical research. Records may have been destroyed by those who hope to protect reputations; the famous erasures on the Nixon tapes by his loyal secretary, Rose Mary Woods, are a prime example. Less purposeful but no less final is the destruction of records by administrators who considered them no longer worth bothering about. Many records never reach appropriate repositories and will not,

therefore, be used; how many records lie buried in dusty file cabinets in the office where they originated or forgotten in some storage area can only be imagined.

Underfunding of archives and records management programs can create major problems. As of the summer of 2006, the National Archives of the United States had over 1,000,000 feet of undescribed records. Those million feet of almost certainly unclassified documents contain useful information on some historians' topics, but they have no way of verifying that fact. A historian should be smart enough to figure out that the records of the Agency for International Development will contain information on United States foreign aid even if there is no guide to them, but in which boxes, folders, and documents the desired facts reside will remain a mystery until they are described at the folder level—unless, of course, the historian is willing to go through, box by box, folder by folder, sheet by sheet, however many hundreds of feet of records there are.

Although many of these limitations are present in the United States today, a rich array of archives is in place, beginning with the National Archives, and includes state and municipal archives, archives of organizations like the Rockefeller Foundation, as well as archives of numerous churches, businesses, and groups. In addition, there are many special collections of the papers of prominent individuals that are either housed in independent institutions like the presidential libraries or have been deposited at some library or archival establishment. Other countries have their own counterparts; the richness depends on the financial resources available and the priorities of those responsible for collecting and preserving the records. These collections make possible historical scholarship, and research in an archives is typically the defining experience of a historian in the same way that field research is usually the defining professional experience for the anthropologist.

Once a relevant source is identified and located, the next question is, is it trustworthy? With modern records, that is rarely a problem. In all probability, the records moved directly from the organization where they were created to the archives. The records themselves may contain information that is untrue or misleading, but the misinformation was either recorded in good faith by a creator who believed it to be true or was recorded by someone who wished to influence an intended reader in a particular direction. It is the historian's job to separate truth from falsehood, to weigh what is in the records, and to compare it with information from other sources. Modern history offers a few examples of deliberate fakes like the Hitler Diaries of 1983, but such frauds are usually detected early.

Earlier sources, however, are more likely to be either fraudulent or altered. In the early modern period, interest in history largely focused on religion and the Church. Concerted efforts to copy and publish manuscripts relating to the lives of saints and the history of the Church began in

the late sixteenth century. These great collective enterprises were carried out primarily by the Bollandists, an association of Jesuit scholars, and the Maurists, a congregation of Benedictines.^[7] Because the souls of men and women were at stake and because the preceding centuries had seen a flourishing market in religious fakes, standards needed to be developed to identify fraud. In defense of his work on the Benedictine charters of St. Denis, Jean Mabillon (1632–1707) published *De re diplomatica* (about Diplomatics) in 1681. This work defined principles for determining the authenticity of medieval manuscripts and charters and in many respects has not been superseded.

TECHNOLOGY

As far as historians are concerned, technology has had both positive and negative consequences. The introduction of printing, by making possible multiple copies of the same document, increased the chance of its survival. The introduction of the typewriter in the late nineteenth century vastly improved legibility. The telephone, on the other hand, has been detrimental. By its nature a telephone conversation is evanescent. Only in the rare cases in which a recording was made or a conversation summarized in a memorandum or other communication is there a record of what was said.

The development of digital records has affected the historical enterprise in the identification of source materials, in access to source materials, and in the creation of source materials. Historians, like those in other fields, have benefited from the creation of machine-readable bibliographic databases brought by the advance of library technology. There are now numerous databases that include indexes to periodical literature, like *Historical Abstracts*, and some that offer the full texts of articles, like *JSTOR*, as well as online bibliographies and catalogs that list books, pamphlets, and manuscript collections, like *WorldCat*. Because they are so convenient and accessible, historians use them far more readily than they ever used their print counterparts.^[8,9] Many guides to individual collections have been made publicly accessible by repositories, like the finding aids for the archives of the American Library Association at the University of Illinois Archives. Some repositories are also making the materials themselves digitally accessible, like the C.S.S. Alabama Digital Collection at the University of Alabama Library (<http://www.lib.ua.edu/libraries/hoole/digital/cssala/main.htm>). And there are programs underway to digitize books, like the Google Book Project and Project Gutenberg, which will increase access to both primary and secondary source books.

As far as historians are concerned, the leading challenge of digital records lies in the third area, digital records as primary sources. Since about 1960 an

increasing proportion of all records has been created digitally, whether the creating body is a government agency, a business firm, or an individual. For many of these records there is no paper equivalent; the electronic voting machine, for example, generates no hard copy register of the votes. As more recent times become the object of historical study, digitally produced sources will increasingly be the sources of the evidence on which historians base their accounts.

Why are they such a challenge? One reason is their sheer volume. The ease of creation of an electronic record, paired with a general trend to ever more documentation by increasingly legalistic and regulated societies, has brought superabundance. Nor is this abundance always well controlled. The physical presence of paper forced individuals and offices to create and use filing systems. Such systems are possible in a digital environment, but individuals appear to use them less consistently.

The inexorable progress of technology, both of hardware and software, brings other problems. Files created before an office's last upgrade often cannot be read. Records were created during the Vietnam War using systems that have long since been superseded and replaced. Their conversion is sometimes possible, but if it is, it is costly. There are also preservation issues. We know the problems the preservation of paper poses; we are only beginning to discover those posed by electronic records. Every other format of information storage degrades; there is no reason to think that digital information will be immune.

HISTORY AND THE PUBLIC

As with many areas of activity, history has popular appeal. Because knowledge of the history of one's own country is regarded as a vital element in the socialization of citizens, some history is included in most high school-level curricula. This practice provides most students with at least a minimum level of knowledge and sometimes stimulates interest in history in later life.

Many publications are available to those who are interested in history. Commercial presses publish numerous biographies and other works of history. Such works involve research, but they are usually written in a more accessible style than works of historical scholarship intended for historians, usually emphasizing the story rather than analysis. Historical fiction is another way in which history reaches a wider audience. It can be very good, like the Captain Horatio Hornblower series of C.S. Forester (1899–1966), or it can be very bad, like the typical "bodice ripper." There are also historical journals intended for the interested public, such as *American Heritage* and *History Today*.

Local history attracts many amateur historians. Many cities and counties have societies dating back to the

nineteenth century that hold meetings and offer history-related activities. Frequently, they publish a periodical or some other type of publication. The county of Somerset in England, for example, has both the Somerset Archaeological and Natural History Society, founded in 1849, that publishes proceedings and various other papers and pamphlets, and the Somerset Record Society, founded in 1886, that publishes transcriptions of original documents relating to Somerset, like the 1342 Feodary of Glastonbury Abbey.

Modern means of communication have also been used to create and to disseminate historical products. Many films and television programs have historical themes; those of Ken Burns are both popular and well-regarded. More and more people are contributing to various oral history programs. Story Corps, a national project of the American Folklife Center at the Library of Congress, is a large scale project intended to encourage people from all walks of life to tell their particular stories.

Popular history also has a recreational aspect. Recreations of battles attract numerous participants. Preservation efforts like Williamsburg and Sturbridge Village, two of the most ambitious examples, attempt to portray life in the past with fidelity and are visited by thousands of sightseers annually.

CONCLUSIONS

What is the future of historical scholarship? In the absence of a crystal ball, it seems safe to predict that its future will be one of both stability and change. The foundational questions, what happened and why did it happen, will continue to be asked as long as humans remain curious about their past. The foundational skills of the historian, the ability to identify questions of significance, the ability to find, select, understand, and evaluate evidence, the ability to argue logically and persuasively and to write clearly are not likely to change.

Change will occur in the questions that are posed. Historical scholarship has always had a presentist bias, a truth expressed most eloquently by Benedetto Croce's famous dictum, "All true history is contemporary history." Experience influences what people deem important; depressions are good for economic history and going to war with a country stimulates curiosity about its past. Different generations will have different priorities and concerns and ask different questions.

Already in progress is change in the sources that historians use. Influenced by the success of historians at using nontraditional sources to study the history of peoples without written records, it is probable that historians will expand the range of types of sources even further to supplement traditional sources. The increased use of primary sources in digital form is inevitable as the events of recent years become the object of historians' interests.

Another realm in which change can be expected is that of theory. Both small-scale theories like the Whig theory of history that viewed history as progressing toward parliamentary government on the British model and world view-type theories like the Marxist theory of history will be replaced by new explanations and newer world views.

Less clear is what can be anticipated in the relationship between the historical writing and the public. The distance between scholarly history and popular history appears to be growing. Although many scholars would very much like to reach a wider audience, it is an uncomfortable fact that what entices readers who are not scholars conflicts with the present canons of historical scholarship.

Historical scholarship has its traditions. Standards of scholarship are well-defined. It is not, however, a discipline with paradigms in the sense in which Thomas Kuhn defined paradigm in his book, *The Structure of Scientific Revolutions* (1962). Ultimately, the individual historian decides which questions are worth asking and how they should be examined. Each has his or her own viewpoint and it is entirely possible for two historians to come to quite different conclusions from the same evidence. As the narrator in Dorothy Salisbury Davis's story, "By the Scruff of the Soul," commented, "history's like a story in a way: it depends on who's telling it."¹⁰

Iowa State University, Ames, Iowa, U.S.A.

Abstract

Society created the library in response to individual, community, and national needs for memory and self-understanding. The development of the library as an institution follows the story of literate humankind and facilitates the telling of the human story in multiple languages and cultures. The library documents growth in intellection and other changes in the human condition. It preserves resources for those of minority as well as majority opinion, ensuring preservation and access for the unorthodox in human affairs. The library respects the full range of human interests and creates networks of resource sharing and international cooperation on behalf of reader interests.

THE ORIGINS OF LIBRARIES

The precise origins of libraries are impossible to trace, although scholars have accumulated knowledge of particular libraries in certain locations. Historians have concluded in general that the invention of writing combined with the impulse to preserve inscriptions have marked the beginnings of the historic era, a period of consciousness about the importance of human memory. The earliest ideas about libraries emerged as a natural outgrowth of interest in preserving such memory, and the library has acted on behalf of society to collect and organize things that are written. The library thus meets a vital social obligation by gathering accounts of the human experience.

DEVELOPING THE INTELLECT: THE ANCIENT WORLD

The creation of libraries likely began with the Sumerians who flourished during the fourth millennia B.C.E. in the region of Mesopotamia between the Tigris and Euphrates rivers. The Sumerians and succeeding civilizations—Akkadians, Babylonians, and Assyrians—inscribed clay tablets using a stylus and imprinting combinations of “wedges” (or Latin *cunei*) into soft clay. With the Sumerian economy based on grain, most of the extant cuneiform tablets describe agricultural transactions. The temples, which were seats of government, stored cuneiform inscriptions in wooden boxes with a tablet labeling the box’s contents. Temple storehouses preserved commercial and governmental documents, hymns, prayers, and incantations, and major literary works such as the *Epic of Gilgamesh*.

In the ancient Syrian city of Ebla, a comprehensive, well-organized royal library housed more than 15,000 tablets. The cities of Nippur, Nuzi, and Mari established similar collections. During the seventh century B.C.E., King Assurbanipal (669–633 B.C.E.), who ruled Egypt and Babylonia and Assyria, established a great library in the capital at Nineveh. Assurbanipal sought to collect every available work relating to cultural, social, and religious matters within his kingdom. His agents scoured the empire to acquire or to copy such works; his scriptorium in Nineveh produced new editions and his library emerged as an encyclopedic collection of human knowledge.

The growth of ancient libraries continued with the Greeks who developed a taste for book collecting and erected a number of Greek temples that featured libraries. In the sixth century B.C.E., Polycrates of Samos and Pisis-tratus of Athens established public libraries. During the Age of Pericles (ca. 495–429 B.C.E.), an emerging book trade supported the growth of private collections by philosophers, writers, and other scholars. Aristotle built an extensive manuscript collection to support his catholic intellectual pursuits. Plato’s Academy and Aristotle’s Peripatetic academy nourished the idea that books were essential to the growth of an educated populace.^[1]

The military conquests of Alexander the Great expanded Greek interest in books and learning to a wider audience, and Aristotle’s organizational scheme provided the basis for the library in Alexandria, Egypt, which would become the most significant library in the ancient world. Founded by Ptolemy I in the third century and brought to fruition by his son Ptolemy II, the museum and its accompanying library swiftly became the premier site for learning and scholarship. Led by some of the major intellects of its time, including the grammarian Callimachus (ca. 305–240 B.C.E.), the astronomer and writer Eratosthenes (276–

194 B.C.E.), and the philosopher Aristophanes of Byzantium (267–180 B.C.E.), the Alexandrian library gathered enormous collections of papyrus and vellum scrolls, which were painstakingly cataloged by Callimachus in his famous *Pinakes*. Eventually, war took its toll on the Alexandrian Library and, by the end of the fifth century C.E., its collections were scattered and lost to the ages.

In Asia Minor, Attalus I (269–197 B.C.E.) and his son Eumenes II (197–159 B.C.E.) established another important library at Pergamum. When Ptolemy II banned the export of papyrus, book makers at Pergamum adopted parchment, which was much more durable since it was made from animal hides, thus marking major progress in preserving library materials. In his history, Plutarch claimed that, with the coming of the Romans in the first century B.C.E., Mark Antony bequeathed to Cleopatra about 200,000 volumes of the Pergamum Library, later absorbed into the Alexandrian Library.

The Romans mirrored Greek interest in books and learning to the extent that Roman emperors—like their counterparts in Alexandria—confiscated and copied books for central libraries. Eminent scholars like Cicero and Seneca created large private collections. Excavations have revealed library rooms in private dwellings in Rome and other major cities throughout the empire. Plutarch and Pliny mentioned that prominent citizens had built extensive private libraries some of which featured separate rooms for Greek and Latin books.

Successful military leaders often acquired books as part of plunder, Mark Antony being the most prominent example. Julius Caesar envisioned the construction of several libraries, some of which were completed after his assassination. The emperors Augustus, Tiberius, Vespasian, Trajan, and Hadrian all established libraries in Rome during the first two centuries C.E. Trajan's Bibliotheca Ulpia, completed about 100 C.E., served as the Public Records Office of Rome until the fifth century. In Byzantium, the emperors Constantine the Great (280–337 C.E.), Julian (331–363 C.E.), and Justinian (482–565 C.E.) sought to expand the holdings of the imperial, patriarchal, and scholarly libraries at Constantinople and elsewhere. Through the efforts of countless scribes and copyists over the centuries, the Byzantine libraries preserved the intellectual heritage of Athens, Rome, and Alexandria, thus preserving ideas from the ancient world and making possible the cultural richness of the Renaissance.^[1]

In South Asia, the Aryans, who had established themselves in the Indus Valley in the middle of the second millennia B.C.E., promoted the growth of Jainism and Buddhism, both religious movements with sacred canons. Libraries and archives soon appeared to help organize and preserve this extensive literature. In China, the Han dynasty (206–220 B.C.E.) endeavored to preserve ancient texts that had often been scattered by warfare in earlier centuries. Han emperors encouraged the writing of literature and developed a culture of meticulous record keeping.

The Chinese created a seven-part classification scheme that organized knowledge into Confucian classics, philosophy, prose and poetry, military accounts, medicine, scientific and occult writings, and summaries. The Chinese later revised this system into four parts: the classics, history, philosophy, and miscellaneous works.^[2]

DEVOTED TO PRESERVATION: THE MEDIEVAL ERA

With the decline of the ancient libraries in the last years of the Roman Empire, the era of great classical libraries came to an end. For the next thousand years the typical European library—which could more accurately be called a “special” library—consisted of several dozen, or perhaps a few hundred, laboriously copied manuscripts housed in monasteries overseen by learned monks. Religious motivations influenced library development in Western Europe during this period. Copies of the Bible along with letters and commentaries made up the contents of these rudimentary collections.

During the first centuries of the Common Era, the classical format of the book changed both in structure—from scroll to codex—and in type of surface upon which words were written—from papyrus to parchment and vellum. The advent of the emerging Christian culture influenced the eventual adoption of this new format, which led to the construction of a portable and easily readable collection of individual books that became the Bible. Thus the texts contained within the codex became more durable and easier to use and to store. They also had the decided advantage of accommodating the contents on both sides of the codex sheet. Books were shelved on their sides, in chests (*archiva*), or on shelves or desks and, as collections grew, the shelving would sometimes occupy the walls of an entire room, often referred to as a *bibliotheca*. At the outset of the Medieval Era, the *libraria* was a licensed distributor or dealer in books, and the *bibliothecarius* was curator or custodian of the collection. Monasteries often provided space for the library and for the *scriptorium* where copyists plied their craft; eventually, the term “librarian” came to denote one who worked with books in an organized collection.^[3]

In the early Middle Ages, two monastic leaders, St. Benedict of Nursia (ca. 480–547) and Flavius Aurelius Cassiodorus (502–597), building on the early precepts of St. Jerome, established rules for transcribing and maintaining manuscripts and general guides for library maintenance. Benedict's rules for copying manuscripts governed that process for the next several centuries. St. Isidore of Seville (ca. 560–636) also wrote standards for operating these fledgling libraries. Such practices continued under the Carolingians, and imperial patronage in Visigothic Spain and Ostrogothic Italy maintained libraries devoted to the preservation of Latin and Greek texts.

More than 220 monasteries existed in Merovingian Gaul although fewer than 300 manuscripts from their collections have survived. By laboriously copying—and thus preserving—numerous classical writings, hardworking monks transmitted an intellectual heritage for future generations. Although the classical texts were not Christian, and therefore considered pagan, early church fathers valued them as precursors of the Christian revelation. By transferring these decaying texts from papyrus to parchment, the church preserved the wisdom of the ancient world.

In contrast to the lands of the Roman West, the Eastern Empire maintained its independence for several centuries, not passing to the control of Islamic forces until 1453. Both Diocletian (245–312) and Constantine (280–337) had promoted the creation and maintenance of imperial libraries at Nicomedia and Constantinople. The great Justinian (527–565) relied on the large palace library to compile his famous code. Photius of Constantinople (820–893) created an influential reference work, the *Myrobiblion*, a classified digest of 280 works. Over the centuries, libraries thrived in great cities and small villages. Given the blending of church and state in the Byzantine Era, it became common practice for imperial and cathedral libraries to organize collections that included secular and religious works. By 1204, the libraries in Constantinople had suffered grievously at the hands of the Crusaders, many never recovering from such devastation.

Meanwhile to the south, a vibrant new civilization was growing from the sands of Arabia based, like Christianity, on the importance of the book. The *Qur'an* encouraged the acquisition of learning and knowledge and, for the Muslim scholar, the private library became essential. Many small libraries were eventually absorbed into larger mosque libraries, the most famous being that of al-Azhar in Cairo, founded in the ninth century. Under the Abbasid Caliphate (750–1258) the *Dar Al-Hikmah* (House of Wisdom) was established in Baghdad in the early 800s. The third most important Islamic collection in the Middle Ages was the court library of the Umayyad rulers of Cordoba, Spain (750–1031), which ultimately boasted a collection of over 400,000 volumes. The steady growth of libraries continued under the Seljuks (1037–1300) and the Ottoman Turks (1299–1923). By the end of the first millennium, Islamic culture supported the construction of numerous libraries, many of which were open to the public. Islamic scholars, moreover, performed an invaluable service for the West by translating Greek and Latin manuscripts into Arabic, thus making them available for future scholars during the Renaissance. The Muslims also acquired knowledge of Chinese papermaking, transmitting this important technology to the West.

While much of Europe sank into cultural depression, King Charlemagne of Frankish Gaul was leading a revival of learning. Under the tutelage of Alcuin of York, who had been influenced by monastery libraries in his native

England, Charlemagne founded a school at Aachen, which established the importance of libraries for learning and scholarship. Thus a new educational system emerged, stimulating library growth in the last years of the millennium. This flurry of intellectual activity led to the founding of libraries at monasteries in Mainz, Salzburg, Fulda, Würzburg, and the famous Abbey of St. Gall in Switzerland, which had been erected in honor of the great Irish monk.

During the eleventh and twelfth centuries, production efficiencies vastly reduced costs, thus making it possible for libraries to acquire more volumes. Cathedrals established schools that took the lead in promoting education among the elite, and their libraries provided resources for learning and the professions. The Carthusians (founded in 1084) and Cistercians (founded in 1098) both instituted special rules for the operation of libraries. Meanwhile, during the late thirteenth and fourteenth centuries, fledgling universities—prompted by the earlier appearance of cathedral schools—began to appear at Oxford, Cambridge, and Paris. The universities sought to supply moderately priced books to students, with libraries playing a large role in obtaining duplicates and cheaper editions to distribute freely to young scholars, and keeping extra copies for themselves.^[2]

The Vatican had maintained a library at the Lateran Palace since the fourth century, but it had been repeatedly sacked by Rome's invaders. During the exile of the papacy to Avignon in the fourteenth century, the limited collections were further dispersed. Vatican librarian Bartolomeo Platina (1421–1481), who served during the papacy of Sixtus IV, reorganized the collection, carefully describing it, making it available to Catholic scholars and convincing Sixtus to establish consistent funding for new acquisitions.

Princely collections emerged in distributed fashion in the years from 1350 to 1500. In the later Middle Ages, kings began to establish libraries in royal residences. Ruling elites expended great financial resources to obtain and house books, prices for which exceeded what most common people could afford. The nobility viewed a fine library as not merely a scholarly apparatus but also a shrine to the word of God or a monument to individual achievement. Resources such as these could enrich research libraries in a later era. Thus, the French king Charles V installed a library on three floors of the Louvre, which would eventually become the Bibliothèque Nationale, and in England, Henry VI donated some of his private collection to King's College in Cambridge.

REDISCOVERING THE PAST: THE RENAISSANCE

Humanists came to dominate the intellectual climate of the fourteenth and fifteenth centuries, regarding the book—its collection, preservation, reproduction, and

distribution—as instrumental in fostering the new learning that would characterize the Renaissance. Humanists devoted themselves to writing and speaking eloquently, to living an upright and moral life, and to serving God as unique individuals, rather than merely as insignificant beings in a massive unfathomable universe.

Seeking fresh perspectives, the fifteenth century reader turned to the classics of ancient Rome and Athens. Scholars rediscovered Cicero, Virgil, Horace, Caesar, and Plato. The advent of the printed book as a result of Johannes Gutenberg's (1400–1468) invention of moveable type in the 1450s—and the subsequent dramatic growth of the craft of printing led by luminaries such as the Venetian Aldus Manutius (1449–1515)—spurred unprecedented expansion in the volume of printed works. This powerful new movement of literary and political expression yielded a vast outpouring of publications in many new subjects which, along with steadily rising literacy rates, promoted libraries as an essential feature of early modern intellectual life.^[4]

In Italy, the Venetian book collector Francesco Petrarch (1304–1374) inspired dozens of other scholars to scour European and Middle Eastern countrysides for Greek and Latin manuscripts. Petrarch's personal library numbered only about 200 volumes but contained significant classical works previously unavailable to scholars. In Florence, Coluccio Salutati (1331–1406) and Niccolò de' Niccoli (1346–1437) built libraries exceeding 800 volumes. In Rome, Cardinal Basilios Bessarion (1403–1472), who was of Greek descent, sponsored the collecting and copying of ancient Greek manuscripts and maintained a personal library of more than 1000 volumes. After the fall of Constantinople in 1453, Bessarion's library was donated to the city of Venice. Subsequently, book collectors helped to unearth and make available hundreds of long neglected classical manuscripts. Many private collectors relied on agents who visited bookshops for rare manuscripts, and the literate classes circulated lists of recently published works.

Niccoli's library became the basis of the magnificent Biblioteca Marciana established by Cosimo de' Medici in the mid-sixteenth century and served as one of the first public libraries in Italy. In 1571 Cosimo's grandson, Lorenzo the Magnificent, founded his own public library in a building designed by Michelangelo. While Renaissance humanists might use the term “public library,” their notion of it was a collection intended for use by the wealthy, the politically connected, cultural elites rather than by the masses of humankind.

In palatial settings, books were often laid open on pulpit-style lecterns and consulted while standing. By the latter part of the sixteenth century, books were placed on shelves, spines facing inward, with notations on the book's title inscribed on the exposed fore-edge. Collections were managed by library workers who created subject catalogs of their contents and who made initial

attempts at classifying books based on prominent subjects such as religious works, canon and civil law, and medicine, followed by philosophy, history, poetry, rhetoric, and grammar.

By the early fifteenth century, the French king Charles V and the British king Henry VI had established royal libraries. In Germany and Central Europe, impressive court collections grew at Augsburg under the influence of the wealthy banker, Jakob Fugger, and at Wolfenbüttel in Lower Saxony, which could boast as its most famous librarian, the philosopher Gottfried Leibniz (1646–1716). Similar libraries appeared in other countries, including the Escorial library in Spain, and in the cities of Vienna, Prague, Munich, and Buda (Hungary). The European intelligentsia developed collections in support of their respective professions. Thus at Ferrara, Italy the physician Nicolò Leonicensio sought ancient Greek manuscripts relating to medicine, and in Seville, Spain, Hernando Colón, son of Christopher Columbus, created an extensive library devoted to ancient and modern geographical sources. Many Renaissance court libraries also housed informal academies filled with collections of scientific instruments.

The growth of libraries during the Renaissance was driven by the dual impact of the printing press and the thirst for both new and rediscovered learning that characterized intellectual life during the fifteenth and early sixteenth centuries. Literate elites sponsored large secular collections which were accompanied by the rise of organized efforts to create bibliographic tools to improve the accessibility of these materials.

NEW HEAVEN AND NEW EARTH: THE REFORMATION

The sixteenth century was a period of intense conflict on the European Continent as the Reformation, beginning with Martin Luther in 1517, shook the very foundations of the established religious order. As a result of the burgeoning Protestant crusade, monastic libraries were damaged, gutted, or razed. The destruction went beyond obvious Catholic Church facilities with even the university libraries in England at Oxford and Cambridge bearing the brunt of anti-Catholic sentiment. The library at Oxford was reduced to such an extent that the furniture was sold, a practical response owing to the loss of so many books. Despite the devastation that resulted from his complaint with Roman Catholicism, Luther fervently supported libraries, and in 1524 he urged in a public letter to all German towns that no expense be spared in establishing good libraries in each community. In response, many new municipal libraries appeared during this time including those at Hamburg (1529) and Augsburg (1537). This period also featured the rise of new universities at Königsberg, Jena, and Marburg, all requiring the acquisition of new book collections.

The rapid expansion of printing promoted the Reformation and the Counter-Reformation as both sides produced thousands of publications to support their positions. Even before 1520, the Catholic Church had sponsored the printing of specialized texts for scholars as well as practical manuals for parish clergy. One significant outcome of the Reformation was the production of numerous translations of the Bible into the vernacular for use among the literate classes. Thus Luther's German Bible appeared in 1534. Meanwhile translations into other languages were published across the Continent: in Dutch (1526), French (1530), Italian (1530), English (1535), and Spanish (1543).^[5]

Although literacy was still limited to upper classes or to those educated in Catholic traditions, the Reformation fostered the production of large quantities of popular literature, intended for the common people, resulting in larger numbers of readers and even greater demand for publications. Religious conflict in the sixteenth century stimulated a remarkably powerful output of printed works which emanated from dozens of skilled printers throughout Europe. This vast literature, combined with steadily rising levels of literacy on the Continent, stimulated library growth at impressive rates. The major libraries grew and consolidated their holdings from smaller, private collections. Examples include the Hofbibliothek in Munich (1558), the Escorial Library near Madrid (1575), the Imperial Library in Vienna (1576), and the Ambrosiana Library in Milan (1609). Still the great libraries were not available to most citizens, only the wealthy or those sponsored by well-connected patrons.

ENLIGHTENING THE EYES: THE SEVENTEENTH AND EIGHTEENTH CENTURIES

The rapidly expanding output of published books during the period of the Reformation merged with renewed interest in study and learning that had grown out of the Scientific Revolution to accelerate intellectual life in the early seventeenth century and contributing to growth in all types of libraries. By mid-century, scientists in England, France, Germany, and Italy were expressing the need to move beyond book fairs and the printed lists of booksellers in order to stay abreast of the latest developments. They established the scholarly journal at about the same time that science was becoming more specialized and diverging from *belles lettres* and philosophy. The scholarly journal would come to disseminate research among intellectual communities, fueling the steady growth of private collections.

Libraries were of two kinds: collections built by the wealthy in their homes and those established to support educational, religious, or governmental institutions. Library workers ceased the chaining of books, preferring to place them in cases lining the walls with spines facing outward. Library collections served elite patrons who

were permitted access during limited hours. Private libraries, such as the one developed by French Cardinal Jules Mazarin (1602–1661), grew large enough to require unprecedented organization. Mazarin's library was directed by Gabriel Naudé (1600–1653) who, in his 1627 treatise on library practice *Avis pour dresser une Bibliothèque*, laid the foundation for arranging and managing private libraries. Naudé recommended that books be valued for their content—rather than for their beauty or rarity—and that they be organized by subject and readily available to those with scholarly interests who themselves may have limited resources for building their own libraries. The collection should be described in separate author and subject catalogs. Presciently, Naudé also proposed that libraries be housed in stable and safe environments, free of dirt, moisture, and noise. Following Naudé's instructions, Mazarin's library eventually opened to the public in 1691 and became the basis for the Bibliothèque Nationale following the French Revolution.

The seventeenth century yielded another library-related classic, one that was destined to take its place among the great documents of humankind. In *Areopagitica* [1644], John Milton (1608–1674) addressed an agency of the British Parliament with a sweeping argument that continues to reverberate. Milton argued for a free press, freedom of mind, freedom of conscience, and that ideas freely expressed and heard and deeply considered constituted the highest order of civil liberty. Milton claimed that even bad books deserve a place, but that one who destroys a good book destroys reason itself, something made, as it were, in the image of God. Although the ideas that he integrated into a whole were not original with Milton, he was the one to present them most cogently and eloquently.

Milton thus developed a theoretical framework for the freedom of the reader and for the protectors of books and ideas as rightly oppositional to forces of suppression. Despite an intrusive (though predictable for his time and place) anti-Catholic rhetoric, Milton provided future librarians, professors, readers, and authors with the conceptual tools necessary to argue for the free distribution of printed materials. An important complementary essay written by John Stuart Mill (1806–1873) appeared in 1859. In *On Liberty*, Mill elaborated on Milton, broadening notions of toleration using as foundational ideas an additional two centuries of liberal thought, yet still advocating restricted rather than unfettered access on the part of young people. In the twentieth century, echoes of Milton and Mill have been heard in official documents of library practice in democratic societies. Concepts of intellectual freedom as articulated by librarians, journalists, and professors have tended to proliferate in those societies grounded in well-defined relationships between society and the individual.^[6]

Among major libraries appearing in the early seventeenth century was the Bodleian Library at Oxford University (1602), steady growth for which was spurred

by its energetic chief benefactor, Sir Thomas Bodley (1545–1613). August, Duke of Braunschweig (1579–1666), founded his library in 1604; it was destined to become one of the finest on the Continent, eventually being renamed the Herzog August Bibliothek at Wolfenbüttel. These were followed soon thereafter by the Ambrosiana Library and the Angelic Library in Rome (1620). Centuries removed, interpretations as to dates of founding may vary as do library names as a result of restructuring and mergers.

In addition to the Bibliothèque Nationale, other nascent national libraries emerged during this period. The library assembled by Friedrich Wilhelm of Brandenburg (1620–1688), starting in 1659, became the Prussian State Library. Catherine II of Russia, an admirer of Voltaire and Diderot, greatly expanded Peter the Great's original collection by capturing as spoils of war the extensive library maintained in Warsaw by Andrej and Jozek Zaluski in the 1790s. The British Museum, which opened in 1753, came about as a merger of the private collections of Sir Hans Sloane (1660–1753), Sir Robert Cotton (1571–1631), and Robert (1661–1724) and Edward (1689–1741) Harley. In 1757 the British Royal Library, which contained works collected by English kings beginning with Edward IV, further enhanced the British Museum's holdings.

The better libraries in early America were assembled by business elites, individual collectors whose books and journals would eventually enrich the great research libraries such as Harvard and Princeton and Yale universities, the New York Public Library, the Library of Congress, and the American Antiquarian Society. Many of the private collectors were motivated by religious interests; the bequest of Puritan minister John Harvard established the Harvard College Library in 1638. Thomas Bray (1656–1730), Anglican minister and bibliographer, devoted to educating clergy and expanding mission work, established some fifty parish libraries throughout the colonies from New York to the Carolinas to Bermuda with about half of them in Maryland. Later he founded some 80 such libraries in England and Wales.

Another movement was underway in North America, that of the social or circulating library. Owned by a private association, books would supply reading matter for members and their families. Benjamin Franklin (1706–1790), scientist and scholar, pioneered in establishing the Library Company of Philadelphia in 1731. Also known as subscription libraries since association members paid fees to become joint owners, the social libraries mirrored similar arrangements in Europe, especially in England where by the mid-eighteenth century more than 250 such libraries were thriving in London and in the countryside. Social libraries established variously by business or working class interests demonstrated the value of reading to an increasingly sophisticated citizenry and became conceptual predecessors to the tax-supported free public library. Robert Keayne's (1595–1656) bequest of 1656 marked an

early attempt to create a library in Boston for use by the public; the collection eventually built was destroyed by fire in 1747.

In the Far East, during the Qing Dynasty reigns of K'ang hsi (1662–1722) and Ch'ien-lung (1736–1795), the Imperial Library, palace collections, and governmental agency collections continued to grow. In 1686 K'ang hsi issued instructions about proper maintenance of the Imperial Library. Western works on science and astronomy were translated and added. Ch'ien-lung's (1711–1799) great contribution was to create the Four Treasures Library, an effort resulting in a definitive collection of 36,000 volumes in Chinese philosophy, history, literature, and other subjects.

REVOLUTION IN POLITICS AND SOCIETY: 1776–1875

The fresh winds of democracy blew across the Atlantic from the new United States of America and into France, and the French revolution resulted in expanded access to reading materials. From the fall of the Bastille in 1789 to 1795, the French wrote 20 decrees pertaining to libraries. Rising middle classes confiscated ecclesiastical property and private collections of the nobility, establishing *dépôts littéraires* throughout the nation. This program was visionary, as it included plans for a union catalog and conceived of the scattered collections in urban and district repositories as a commonly held national resource. Two major developments emerged; one involved vastly expanded middle class access to books with middle class defined as white males. The concept of free public libraries also arose, with more robust expressions in Paris than in the countryside. But many provinces had municipal and parish libraries, some of which escaped confiscation due, only in part, to having been considered of minimal value.^[7]

A second major trend in the politics of nation building was the movement to establish central libraries with national level responsibilities. In the years from 1793 to 1795, the Bibliothèque Nationale won authorization to obtain first manuscripts and then books from throughout France. Central libraries with nationalizing impulses also arose in Lisbon (1796), The Hague (1798), Washington, DC (1800), Budapest (1802), Buenos Aires and Rio de Janeiro (1810), Oslo (1811), Santiago de Chile (1813), and Reykjavik (1818). In the leading cities of Russia, private collections formed the basis of the Imperial Public Library, opened in 1814 in St. Petersburg, along with the N.P. Rumiantsev Library founded posthumously in 1831 and transferred to Moscow 30 years later as the core of the Lenin Library. With the British Museum (more recently the British Library) as forerunner, these national institutions gradually assumed the role of keepers of the cultural record and as leaders in organizing collections and services and in training staff.

The Industrial Revolution in the early nineteenth century brought an influx of rural populations into the great cities of Europe and North America. Millions left the farm, seeking employment in the factory and economic and educational opportunity in the city. Crowded conditions among the new urban masses exacerbated crime and illiteracy. Multiple social responses, both secular and religious, incorporated the tools of self-enlightenment: reading and the distribution of literature, a robust popular press, lyceums, books clubs, and libraries. Literacy emerged to stimulate social critique, but also to quell urban unrest and acculturate youth into the national ethos. Reformers distributed small portable libraries which featured moral instruction but other topics as well.

Reformers also established mechanics institutes representing the reading interests of working class males but most such organizations were eventually absorbed by middle class business interests. The Society for the Distribution of Useful Knowledge (SDUK), established in England in 1826, promoted the expansion of reading and libraries for the working class. In 1839 the SDUK issued *A Manual for Mechanics Institutes*, an early analysis of the value of resource sharing. The *Manual* recommended interlibrary lending that incorporated cathedral libraries, county seat collections, municipal archives, the holdings of book clubs, and the reading rooms of religious denominations.

The Sunday school movement promoted literacy for both genders, something that mechanics', businessmen's, and early subscription libraries had failed to do. The interdenominational Society for Promoting Christian Knowledge (SPCK) had been active in England and Wales for more than a century. The Wesleyans, Presbyterians, and Episcopalians established circulating libraries in North America. Sunday school libraries, partially dependent on the societies, featured not only biblical studies and moral rhetoric but also light fiction, drama, and contemporary nonfiction. In early nineteenth century England, the Religious Tract Society rivaled the SPCK as a distributor of evangelical publications. Sunday schools reached socioeconomic strata below the middle classes and, in fact, provided models for literacy instruction among ethnic minorities. Sunday schools were also among the earliest organizations to take seriously the reading interests of children and young adults in part because of their intense focus on moralistic and middle class behavioral norms. By 1850 Protestant denominations had established more than 2000 Sunday school libraries in the United States and adjoining territories.

Public education at the elementary and secondary levels obtained governmental support, laying the foundation for apprenticeships, vocational training, and civic participation, and providing school libraries. By the 1850s the English common school movement had spurred the establishment of libraries especially in secondary schools. Local control played a larger role in school library support

in North America than it did in Europe and the Far East where national leadership became a more powerful determinant.

In the nineteenth century German universities thoughtfully took library functions beyond custodial and scholarly interests. The University of Göttingen established policies to expand professorial and student access. American student, and later founder of the Boston Public Library, George Ticknor (1791–1871) was made to feel welcome enough that he came to regard Göttingen's rich collections as a common treasure not merely for Germany but for the entire world of scholarship. German intellectuals, moreover, sought a wide audience by publishing encyclopedias intended for home use, thus making feasible a collection of searchable knowledge and practical information for the nuclear family.^[7]

PROFESSIONALIZATION AND GROWTH: 1876–1988

Landmark events in 1876 marked the dawn of a new era in the professionalization of librarianship. Melvil Dewey (1851–1931) developed a system of classification on the concept of relative location, thus rendering obsolete earlier fixed-location arrangements. Published in 1876, the Dewey Decimal Classification (DDC) found ready acceptance throughout North America. The year 1876 also marked the first issue of *American Library Journal*, retitled *Library Journal*, the first journal in the United States devoted solely to library topics. At the same time, the United States Office of Education issued its massive report, *Public Libraries in the United States of America, Their History Condition and Management: A Special Report of the U.S. Commissioner of Education* [1876], thus launching a large body of professional literature rooted in historical precedent, in contemporary best practices, and in commonly held yet often conflicting assumptions about the social and political purposes of libraries. Librarians established the American Library Association (ALA) in 1876, the first national conference of library practitioners since 1853, which began annually thereafter to address current issues, and to promote the growth of libraries and, to a lesser extent, the professional and economic development of library workers. The Library Association was established in Great Britain in 1877. With the emergence of a professional literature and professional societies, the foundation was laid for the unprecedented expansion of libraries and for the education and training of library workers throughout the English-speaking world.

The editors of *Public Libraries in the United States* considered a public library as any library to which an individual could gain access, a view inclusive enough to incorporate mercantile and subscription libraries, academic libraries, and specialized libraries such as those devoted to law, medicine, and theology. In the year 1876

the origins of such libraries could be traced back more than 200 years. But the tax-supported free public library was altogether different according to William Frederick Poole (1821–1894) who claimed that the free libraries of Europe had served the intelligentsia, rather than the masses, and had not been supported by taxation. Perched atop the public libraries of first Cincinnati and then Chicago, Poole defined the public library much as we know it today—established by state legislation, supported by local taxes and by gifts, and maintained for citizens invited to share equally in its intellectual bounty.

Kathleen Molz describes the tax-supported free public library as essentially an Anglo-American phenomenon, an ameliorating influence responding to the Industrial Revolution in Britain and the United States, an influence associated with reformers who also opposed slavery and promoted education for youth and better treatment for the mentally ill. She observes that the public library movement gained momentum at about the same time in both England and in New England with enabling legislation from the British Parliament in 1850 and 1855 and with locally supported municipal libraries in the United States. Among the American pioneers were Salisbury, Connecticut and Peterborough, New Hampshire, although the first major metropolitan public library opened its doors in Boston, Massachusetts in 1854 and soon emerged as worthy of emulation.^[8]

The Boston Public Library has attracted the attention of historians for another reason—research into the motivations of founding elites. In the 1970s Michael Harris studied the Boston Public Library, challenging the previously accepted view of the Library as essentially altruistic, committed to providing reading materials that responded to democratic impulses for political participation and economic opportunity. In “The Role of the Public Library in American Life: A Speculative Essay” Harris pointed to more sinister purposes, that elites created libraries to inculcate compliance from the citizenry, a willingness to accept the *status quo*, not challenging dominant political and cultural norms.^[9] A revisionist perspective on social and political purposes thus entered public library historiography and *The Journal of Library History, Philosophy, and Comparative Librarianship* [commonly referred to as *JLH*] recorded much of the vibrant conversation advanced by Elaine Fain,^[10] Michael Harris,^[11] and Dee Garrison^[12] in 1975, Edward G. Holley^[13] in 1977, and Michael Harris^[14] and Phyllis Dain^[15] in 1978.

In collegiate education, Germany had provided a model for her European neighbors and for North American institutions of higher learning in the late nineteenth and early twentieth centuries. Research as a university ideal came first alongside undergraduate liberal arts education then, in many places, eclipsed it. The Universities of Göttingen and Tübingen, for example, led evolving conceptions of critical historical and literary analyses. Germans refined the seminar method of teaching, which featured graduate

students making presentations based on examination and comparison of original sources. The intellectual structure for seminar methods was rooted in disciplinary expansion; the social sciences spawned the new disciplines of sociology, economics, political science, and psychology, all of which were growing increasingly sophisticated and examining new paradigms.

German universities attracted scholars from across the globe to pursue studies in the humanities and the emerging social sciences from new, more scientific perspectives. Herbert Baxter Adams (1850–1901), a Johns Hopkins University professor and founder of the American Historical Association, joined the trek of Americans who returned from Germany to the States with the gospel of scholarship for expanding academic libraries into strong retrospective collections organized around disciplinary strength. Rationales for seminar libraries followed inevitably especially from 1880 to 1920 when the broad outlines for the modern university began coming into view, and when new university library buildings featured interior reading rooms organized by discipline and later referred to as subject departmental libraries. Seminar libraries had become powerful symbols of institutional commitments to doctoral research and teaching.

Historians of higher education acknowledge the Social Gospel and Progressive periods as encompassing the formative phases for higher education and its libraries and the twentieth century as the time when university research libraries—based on internal organization and collection size—came to full maturity. Kenneth J. Brough chronicled the transition of the American university library from storehouse to workshop in *Scholar's Workshop: Evolving Conceptions of Library Service* [1953]. He explored the history of the ideas, notions, terms, and phrases for the university library, providing metaphors for its purpose in academe.^[16] The leading American university research libraries, based on the depth and range of printed collections, include private universities Harvard, Yale, and Stanford, and public universities Illinois, Michigan, and California at Berkeley. And in the United Kingdom, Oxford and Cambridge had long since set the standard for collections, having been established in the Middle Ages. In 1918, the British Parliament established the University Grants Committee for institutions of higher education throughout England, expanding the national role in financial support. In Italy an 1889 statute had created a council at each university governing library book expenditures. These models differed substantially from the more diverse methods in the United States, which relied on combinations of local, state, and private support.^[7]

The Industrial Revolution dominated life in Europe and North America in the late nineteenth century. In those nations most advanced economically, industrialists combined technological innovation with mass production as they constructed factories in big cities. Population centers swelled to unprecedented proportions, creating new

wealth amidst unrestrained business expansion. On occasion, a wealthy industrialist would demonstrate civic virtue and cultural influence by supporting colleges, museums, and libraries. One such leader was steel magnate Andrew Carnegie (1835–1919) who contributed funds to construct 3000 library buildings in Canada, England, Ireland, and the United States.

Carnegie used his library contributions to refine the relationship of the municipal library to its constituents and to expand the public library movement throughout the English-speaking world. Precursors of the tax-supported free public library had featured 1) subscription libraries serving upper and middle class, and sometimes working class, interests for members only and 2) municipal reference libraries dependent on wealthy philanthropists. By implementing the requirement that grant recipients collaborate with local governments to elicit tax revenues for library maintenance, Carnegie underscored the value of public–private partnerships but also the importance of continuous public support for cultural institutions. With a new Carnegie library building, even the smallest village was afforded the opportunity to promote literacy, leisure reading, adult education, and political engagement with an institution that stirred a sense of civic pride and accomplishment.

As the great cities had attracted burgeoning populations seeking opportunity, so also they attracted the social problems that followed in the wake of humans as economic commodities in the great industrial engine. The unrestrained rise of industrialization, immigration, and urbanization had created dislocations that permeated Western nations. Individuals felt keenly the loss of belonging and social control formerly inhering in towns and neighborhoods, schools, and churches. Citizens sought order amidst unprecedented change; they felt deeply a loss of community; and they came to see the professions as vital ameliorating influences.^[17] A better life, it was hoped, would require more nurses, social workers, teachers, and librarians, thus giving rise to formal education for the helping professions and exemplifying the best Victorian impulses to exercise social control through service for the commonweal.^[18]

Educating Library Workers

Since earliest times, aspiring librarians had been apprenticed to the directors of large libraries on the premise that those who oversaw the largest collections dealt with matters of greatest complexity in processing and housing collections, and in making them available to readers. Simultaneously, bibliographers and other library workers continued to develop the core information that would come to be used in formalized training. The writings of Gesner and Naudé advanced this thinking, accompanied by the writings of book collectors, scholars, and philosophers who offered larger intellectual perspectives

and thus helped to establish foundational requirements for practitioners.

As the search for new ideas about the meaning of librarianship intensified, the resulting information provided frameworks for formal instruction. As early as 1821, the *Ecole des Chartres* in Paris offered conceptual development in the form of archival training. During the early and middle years of the nineteenth century, increasingly nuanced ideas were advanced by the Germans Martin Schrettinger (1772–1851) and Friederich Adolph Ebert (1791–1834), the Danish scholar Christian Molbech (1783–1857), by the Italian Antonio Panizzi (1797–1879) who directed the British Museum, and by Charles Coffin Jewett (1816–1868) in the United States.

As important as these contributions were, they could not match Melvil Dewey's power to educate and to otherwise influence rising generations of library workers. His conceptual grasp of classification and early adoption of standardization laid a solid foundation for library training, a program he launched at Columbia College in 1887 and later moved to the New York State Library in Albany. Dewey had observed vast public and school library movements spreading across a growing nation; he saw the educational potential of libraries and the employment potential of educated librarians. He would prepare individuals for frontline services: his graduates would create catalogs—the essential finding aids for local collections—and they would teach and assist readers and oversee reading rooms. The librarians would become resourceful guides for inquisitive citizens in the big cities and small towns of the rapidly expanding Industrial Age. Though Dewey may have been North America's most visible library educator, he did not labor alone. Indeed, a number of library schools appeared around the turn of the century and soon thereafter, some of them in the public libraries of major cities including Atlanta, Los Angeles, New York, and St. Louis.

Schools flourishing during the first generation of American education for librarianship rode the wave of emphasis on efficiency in business and civil service reform when government workers advanced beyond political patronage into more professionalized settings. The intellectual foundations for library training were quite rigorous and, in fact, schools often required tough entrance exams that assumed knowledge of history, literature, geography, the arts, and foreign languages. Thus early graduates promoted dominant cultural values and mastered the multiple routine tasks that marked librarianship as an entry-level middle class profession. Library education worldwide sprang from independent schools—some of which emulated Dewey and his counterparts—in Munich (1905), Leipzig (1914), Copenhagen (1918), London (1919), Padua (1922), and in Wuhan, China (1920). By the mid-twentieth century many schools had moved into university masters' degree programs. While the master's became the basic requirement for practice in public, academic, and special

libraries, undergraduate programs also trained librarians, especially for school libraries, and a small number of nations and states admitted practitioners through examination.^[19]

Meanwhile, an alternative model for educating library workers was offered by the redoubtable Karl Dziatzko (1843–1903), a German scholar and early adopter who organized cataloging records by interfiling slips alphabetically. In the 1870s Dziatzko restructured library collections at the University of Breslau. By 1886 he was at the University of Göttingen presenting scholarly lectures for librarians-in-training, moving beyond the older systems of patronage and apprenticeships. Holding professorial rank, Dziatzko rooted his lectures in classical scholarship and descriptive bibliography, offering for the Continent a more intellectual approach than either Melvil Dewey or the training programs provided under the aegis of urban public libraries. Unfortunately, the German bibliographer never created a full curriculum and never attracted wide interest on the part of prospective librarians. More scholarly iterations of library education lay dormant until 1926 when the Carnegie Corporation funded the first doctoral program in librarianship at the University of Chicago.

Women Working

Library training programs succeeded in attracting large numbers of females into the profession. As with other helping professions, librarianship was thought by contemporary opinion leaders to be especially suited to women who sought employment beyond home and whose gender traits it was argued were appropriate for successful practice. A male-dominated profession in the nineteenth century and earlier, librarianship transitioned quickly to become female-intensive.

Female participation in the profession has reflected dispositions in the society at large, that women have suffered from discriminatory attitudes and practices. From the earliest years of the twentieth century, according to Mary Niles Maack in “Gender Issues in Librarianship,” the library press reported on the absence of women in the top administrative posts of the largest libraries. Maack underscored instances of “hierarchical discrimination,” recalling that in 1952 the Public Library Inquiry had documented a dual career structure for males and females and that, in 1987, males constituted 73% of the directorships of member university libraries of the ARL (Association of Research Libraries).^[20] The term “glass ceiling” came to describe the barrier faced by women librarians possessed of administrative talent but, due to systemic ideologies arrayed against them, were denied the opportunity to exercise that talent at the highest possible levels.

Maack also identified “territorial discrimination” as the sequestering of women into technical processing and children’s and youth services, regarded by many as roles well-suited to female attributes. Another type of territorial

discrimination has been the dispersal of professionals by type of library with men predominant in settings with higher social status, university research libraries, and with women often clustered in less prestigious workplaces such as small public libraries.

Recent scholarship devoted to the history and biography of women librarians has confirmed their skill as resourceful promoters of library services that extend beyond well-connected elites. The impulse of women to transcend the boundaries of gender, class, and race has influenced cultural life as varied as that in China, India, France, Germany, Nigeria, the United States, and the states of the former Soviet Union. Historical precedent has combined with civil rights movements, feminist theories, and case law to provide new tools for the profession to create more equitable settings for women library workers.^[20]

Twentieth Century Expansion

Much of the world was engaged in all-consuming war during the early years of the twentieth century. Governments also waged ideological battles, with democracies competing with socialism, fascism, and with repressive governments on virtually every continent. During World War I, libraries supported the war effort with their own special expertise. The American Library Association collaborated with the American Red Cross, the Y.M.C.A., and other social service agencies to support troops through book distribution programs. Librarians shipped 1.5 million books overseas and processed additional millions for libraries for more than 600 military encampments and seagoing vessels, a process that transformed ALA into a much more robust organization.

Military services and related support functions stimulated the expansion of governmental libraries of all types, especially among dominant nation states. These subject collections ranged from patents, to social science data, to foreign affairs, to classified documents. Some of the great libraries in the U.S.S.R., for example, were in Moscow, collections devoted to the social sciences, the sciences, agriculture, and military affairs. Among the finest special libraries in the world were those held by the British Museum. Others of special significance in the United Kingdom include libraries of the Royal Society of Medicine, the Royal Geographical Society, and the School of Economics at the University of London.

Libraries experienced dramatic growth after World War II in the years of economic expansion and the Cold War. Massive federal subventions were designed to prepare nations in the fight against opposing ideologies. Much more was at stake than merely differing points-of-view. The United States and the U.S.S.R. had developed weapons of mass destruction, challenged each other for technological superiority in space, and fought wars of proxy while literate societies began to process the

meaning of the Holocaust, and the Israelis carved out of Palestine an economically viable but constantly threatened militarized state. Nations committed support for all levels of education as part of larger movements to establish economic and military superiority. Librarians frequently argued for greater library support as vital to national security, military power, and economic expansion. Libraries devoted to technology and science enjoyed unprecedented growth; a number of academic libraries doubled in collection size every 20 years. During 1968 on college campuses in the United States, 68 major building projects were underway; during 1993, 25 years later, that number had risen to 100.^[21]

Sharing Resources

The modern idea of bibliographic control of a library's holdings has developed slowly over the centuries culminating in today's policies and tools for classification, cataloging, and complementary means of bibliographic description. Librarians have come to value such tools, understanding that the local collection rarely meets every request of the local reader, and have thus sought to meet the needs of multiple readers by sharing resources. Since the days of the Sumerians, library keepers were assisting readers in finding materials of interest. This task became especially complex during the Renaissance as the great increase in secular knowledge, produced by a small army of publishers springing up throughout the Western world, resulted in vast new amounts of reading materials and expanding library collections.

The idea that a single volume could guide the inquiring reader and encompass all human knowledge was an idea that had attracted a number of scholars including Konrad von Gesner (1516–1565). In 1545, he published *Bibliotheca Universalis*, a catalog in Greek, Hebrew, and Latin intended to identify all writers (with titles of their works) who ever lived. What may have been the first printed catalog of an academic library appeared in 1595 at the University of Leiden. Most catalogs of this period were arranged into general classes such as theology, medicine, philosophy, and history and then subdivided by the size of the volume. Thomas James (1573–1629), the energetic first librarian of the Bodleian Library, was encouraged by his benefactor, Sir Thomas Bodley, to devise more detailed listings of that library's holdings so that, as a result of book-buying tours of the Continent, the Bodleian would not duplicate what it already owned. The 1620 catalog was likely the first catalog arranged alphabetically by title, an approach vastly improved by 1674 when Thomas Hyde (1636–1703) and later Thomas Hearn (1678–1735) added cross-references to the alphabetical title lists.

A landmark event in resource sharing was the adoption of individual cards to replace entries in static printed volumes, thus providing flexibility and currency in catalog

information. Led by such early leaders as Charles Coffin Jewett and Charles Ammi Cutter (1837–1903), American libraries had, by the end of the nineteenth century, begun replacing their printed catalogs with cards. This change yielded fresh interest in improving the description of cataloged works. Sir Antonio Panizzi's groundbreaking 1841 *Catalog of Printed Books in the British Museum* laid the foundation for later efforts by Jewett in 1853 and Cutter in 1876. Influenced by Panizzi and by the 1871 *Prussian Instructions*, catalogers continued to revise rules in subsequent years and throughout the twentieth century. Revisions included those of the American Library Association's *Catalog Rules: Author and Title Entries* (often called the 1908 code), a 1941 revision (sometimes called the 1941 draft code), the 1949 *Rules for Descriptive Cataloging in the Library of Congress*, the 1961 International Conference on Cataloguing Principles (known as the *Paris Principles*), and the well-known 1967 *Anglo American Cataloging Rules*. In 1978 AACR was revised to become the AACR2 which itself was revised in 1988, 1998, and in 2002. Complementary developments included standards for monographic description as reflected in the 1974 International Standard Bibliographic Description which was later applied to nonbook sources.^[22]

Description represents only half of the challenge of establishing bibliographic control. The other half is the use of classification to facilitate location in a specific library. A number of classification schemes have been invented with that of Melvil Dewey becoming most widely accepted. While at Amherst College, Dewey created his Dewey Decimal Classification (DDC) which has undergone numerous revisions in order to update nomenclature and concepts, and has become popular in American public, school, and academic libraries. The Library of Congress (LC) developed its own system, drawn initially from an arrangement by Thomas Jefferson (1743–1826) whose approach to classifying knowledge had, in turn, been rooted in concepts of knowledge articulated by Sir Francis Bacon (1561–1626). The LC system was greatly elaborated in the early twentieth century by J. C. M. Hanson (1864–1943) and Charles Martel (1860–1945). In 1901 the Library of Congress began distributing copies of cards to libraries throughout the nation, one important result being the widespread adoption of the LC system especially in academic and research libraries. Other classification systems were the Colon Classification developed by S.R. Ranganathan (1892–1972) in 1933 and the Bibliographic Classification of Henry Evelyn Bliss (1870–1955), which appeared in segments between 1940 and 1953.^[23]

By the late nineteenth century, librarians as a learned community had begun to seek professional growth through the formal exchange of ideas both practical and philosophical. Enthusiasm at the inception of the American Library Association spread across the Atlantic Ocean to the first International Conference of Librarians in

London in 1877. Attendees represented the United Kingdom, and the United States as well as Australia, Belgium, Denmark, France, Greece, and Italy. The opening session credited the Germans for contributing the term *bibliothekswissenschaft*, translated “library science.” Participants established The Library Association of the U.K., taking note of the differing perspectives of their American counterparts. A second international conference hosted in London in 1897 drew 641 (more than twice the attendance 20 years earlier), representing the Far East as well as Europe and North America. Conferees presented papers on administration, architecture, bibliography, cataloging and classification, children’s services, education for librarianship, employment opportunities, and public services.^[7]

Cooperative enterprises advanced considerably as a result of the International Conference on Bibliography (Brussels, 1895) which, in turn, established the International Institute of Bibliography (IIB) to develop a universal bibliography on the structure of Dewey’s classified subjects. Paul Otlet (1868–1944) and Henri La Fontaine (1854–1943) negotiated with Dewey to adapt the fifth edition of the DDC in order to develop the Universal Decimal Classification (UDC) which they completed in 1907. The UDC, a faceted scheme, was especially well-suited to scientific and technical subjects, and has been widely adopted throughout the world, particularly in Europe, French-speaking North Africa, Spain, and Latin America.

Otlet and La Fontaine pursued a number of educational and organizational ideas, establishing, in 1910, the Union of International Associations. The IIB itself continued UDC development in French, German and English and later became the International Federation for Information and Documentation (FID). The FID subsequently affiliated with other international organizations such as UNESCO (United Nations Educational, Scientific, and Cultural Organization) and IFLA (International Federation of Library Associations and Institutions). In the 1960s and 1970s, FID, IFLA, UNESCO, and others collaborated on library education for developing regions, establishing and strengthening programs in China, Ethiopia, Indonesia, Jamaica, Morocco, Nigeria, the Philippines, Senegal, Uganda, and Venezuela.^[24]

In the 1960s in the United States, the Library of Congress led a collaborative effort to create the MARC (Machine-Readable Cataloging) format. With MARC records as a standard, two American networks began distributing online bibliographic records contributed by member libraries: OCLC (Online Computer Library Center, originally Ohio College Library Center) and RLIN (Research Libraries Information Network), affiliated with the Research Libraries Group. OCLC emerged as the core database provider for regional networks, most of which provided a broad range of services including preservation, document delivery, and continuing education. Varieties of MARC were adapted for the United Kingdom, Korea, and other nations, further enriching what functionally became

an international database, a vitally essential tool for resource sharing.

Serving Diverse Populations

Ethnic minorities routinely confront multifaceted challenges to economic and educational opportunity, a truism in both free and totalitarian nations. Such circumstances of daily existence describe, for example, Iranians in the United Kingdom, Palestinians in Israel, and African Americans in the United States. Libraries hold the capacity to preserve racial memory, enhance ethnic pride, and acculturate immigrants into the national ethos. The histories of urban public libraries, such as Phyllis Dain’s *The New York Public Library: A History of Its Founding and Early Years* [1972], feature discussions of ethnic collections and services to immigrant populations. The role of the librarian, extrapolating from Dain’s account, embraces an appreciation for every minority perspective however misunderstood or unusual. Thus, without ignoring the interests of the majority, the librarian incorporates peace literature into a military library, or resources on Islam in a predominantly Christian community, or Hispanic materials in a largely Caucasian city. The library, as it provides resources for minorities, becomes a harbinger of economic and intellectual mobility. A reference source such as the one by Stephan Thernstrom, Ann Orlov, and Oscar Handlin, eds., *Harvard Encyclopedia of American Ethnic Groups* (1980) provides entry into the multiple layers of minority status; and E.J. Josey and Marva L. DeLoach, who edited *Handbook of Black Librarianship* (2nd. ed., 2000), provide a well-informed guide to collections and services for one particular minority culture.

The task of the librarian who would serve the citizens of a pluralistic, multicultural readership constitutes a balance of the tension between advocacy and neutrality. The librarian advocates for access on behalf of the reader who explores the unorthodox in politics, theology, art, sex, and other areas of human interest. At the same time, the librarian—understanding issues of authority and credibility—does not discriminate as to content, preferring as highest priority the task of bringing readers together with the subjects they pursue, regardless of where reader interests might lead. This work is highly political, requiring that people of courage promote professional ideals. Sam Walter Foss (1858–1911) illustrated this professional tension at its best. He wrote that the librarian

is both Greek and Barbarian, Jew and Gentile, realist and romanticist, aristocrat and democrat, theosophist, secularist, orthodox, liberal, populist, and patrician. . . . the janitor of an amphitheater where warring creeds, beliefs, and tastes contend like gladiators. [The librarian] champions none and antagonizes none, but simply keeps his amphitheater in good repair and takes a sportsman’s like delight in seeing the fight go on.^[25]

GLOBALIZATION: 1989–PRESENT

Two cataclysmic events in 1989 signaled the arrival of a new age: 1) political revolt in China, fueled by students, professors, and labor activists who had been communicating, in part, through e-mail, culminating in the Tiananmen Square Massacre, and 2) the destruction of the Berlin Wall, the reunification of Germany, and the dispersal of the nations of the U.S.S.R. into independent states. These events symbolized unprecedented intellectual and economic exchange transcending geopolitical borders and barriers of ethnicity, language, and culture. The internet expanded from scientific and military uses into general business and educational purposes, transforming the way the world conducts its affairs. Commercial entities that never before existed came to redefine for-profit and not-for-profit institutions. Thomas L. Friedman heralded the new age in his synthesis, *The World Is Flat [Updated and Expanded]: A Brief History of the Twenty-first Century* (2006). Reading material provided by librarians became available in digital form, accessible anywhere one could find a computer with an Internet connection, no longer bound by a printed or film-based format.

The new age also marks new expressions of religious, economic, and political fundamentalism and militarism. The world of the twenty-first century is as dangerous as in any previous time. Libraries that would pursue successfully their highest ideals require open societies characterized by relative political and economic stability. War, terrorism, and natural disasters destroy libraries, books, the freedom to read, and the unfettered pursuit of ideas. These valued object lessons appeared in sharp relief at Library History Seminar XI, an international symposium hosted October 27–30, 2005 by the University of Illinois Graduate School of Library and Information Science. Hearing tales of fire and flood, bomb and bayonet, conferees recalled once again that the challenges to progress are relentless, but also that the purposes of libraries and the lessons of history have become a narrative intertwined.^[26]

WHY SOCIETY NEEDS LIBRARIES

The meaning of the thousands and thousands of stories that make up the library narrative lies embedded in the human impulse to record transactions, experiences, and ideas. Persisting issues in the imperatives to collect and preserve involve the processes and criteria for deciding what content merits preservation, at what levels of expertise and support, and within which formats. The first edition of a literary classic, for example, receives a form of storage, organization, and access that differs from that afforded a current municipal telephone directory. Choices about things to keep, things to treat in a special way, and

things to discard must never be made in a vacuum. Such decisions rely inevitably on a mixture of professional perspectives and individual and collective judgments in the context of institutional, cultural, economic, and political priorities and realities. The complex of factors influencing the nature of library collections is thus rooted in historically understood concepts of the library's function in society.

The Library as Repository

Michael Harris defines the library as a collection of graphic materials, intended for specific readers, and that is cared for by individuals familiar with those materials and engaged in making them accessible.^[21] The Harris definition may be usefully enriched with the notion of the library story as a foundational chapter in books devoted to the growth of civilization. Pierce Butler (1886–1953) wrote that the library came into existence to meet society's need to preserve accumulated human experience and to transfer it to succeeding generations who would adapt it for contemporary use. The library was a legacy for the living. The story of the library became a narrative with historic roots in people, ideas, and broad environmental trends, yet also with an eye to future generations as a matter of moral obligation.^[27]

David Reith has argued that, since the library emerged from a complex of values and social organization, the elements of its structure connect by their nature to cultural phenomena or to components of the social structure.^[28] Reith posited the fundamental purpose of the library as a repository, that the library collects and preserves the full range of expressions of human curiosity and intellect, yielding a plethora of resources essential for individual, community, national, and global progress. While some results of human creativity (i.e., art, music, patents, or pharmaceutical formulas) may reside in museums, digital repositories, or research centers, they have, at the root of their creation and distribution, a content-based structure that a specialist can adapt for storage and retrieval. While library classification and arrangement share some concepts with those of museums and archives, the latter institutions are bounded by concerns for format that the library—with its ultimate focus on content—does not share. To place a high value on the organization of materials goes to the very heart of a library's purpose since it considers the interests of future readers in ways that transcend the boundaries of language, culture, ethnicity, gender, ideology, and time.

The Library as Change Agent

The library has also possessed capacities as an agent of change, assuming a dynamic rather than a static universe, and thus a vital work of the library becomes documentation of that change. Although appearing on the surface as a

passive and dependent institution, the library has also challenged the status quo, having promoted revision of economic, political, educational, or social norms. The library as change agent represents an important interpretive departure from an earlier view of the library, the public library in particular, as a follower of change rather than a creator of it.^[29] While consensus about the library as an agent of change or a follower of change might be elusive, consensus about the library as serving the common good might be more tangible. Historically that good has been regarded as inherent, something understood intuitively by the library and its constituents though too seldom stated in the public square.

The story of the library as an advocate for change is rich with political ideas including that, for example, during the late nineteenth and early twentieth centuries in the United Kingdom and the United States, the library should support the national interest by helping to assimilate immigrant cultures and ethnic minorities, teaching new arrivals the language of democratic participation and economic stability. More recently, library collections have nurtured the goals of civil rights for women and ethnic minorities, for people with physical disabilities, and for those with gay, lesbian, bisexual, and transgendered preferences. This makes the library a potentially safe haven and valued resource for those threatened or intimidated by dominant social behaviors, but these value commitments may also make the library an unwelcome target of suppression by fundamentalist impulses. Since libraries depend on the societies into which they are integrated by politics, economics, and ideology, they are rarely positioned for unfettered allegiance to professional ideals but rather offer mixed policies, sometimes promoting change by advocating for minority interests and sometimes limiting change by appealing to the powerful and well-connected.

The Library as Educator

Another role for the library involves that of education, a role that is at once both noble and suspect. Stakeholders in democratized settings tend to disagree about the values the library as educator should promote. Consequently the library, depending on its environment and those interpreting its purpose, has either educated readers to higher levels of perception and understanding or it has suppressed information that readers would find helpful in pursuit of opportunities for intellectual, economic, or political growth.

The librarian as a promoter of certain values, as someone who chooses an educational objective and then pursues that objective by building and promoting collections of a particular character or who simply discerns within an existing collection certain educative potential, is a concept that intellectual and social historians have come to explore with increasing nuance. Seminal monographs by Dee

Garrison,^[30] Evelyn Geller,^[31] Wayne A. Wiegand,^[32] and Louise S. Robbins^[33] analyze ambivalent perspectives that have marked the library as promoter of an educational ethos with programming and collections that target identifiable constituents.

In the face of misuse of the library as an educator, it must be recognized that the great religious movements possessed a powerful instructional obligation, honoring the written word, the creeds and liturgies and other sacred writings of prophets and priests. In fact, most religious traditions deserve a debt of gratitude for preserving classical secular texts in literature, history, economics, and government in addition to theological treatises. Scholars and scribes transmitted literature from the past, often migrating content to more durable media, performing such tasks as matters of educational purpose as well as religious observance. Claims to cultural reproduction in this particular way mark the stories of Eastern religions such as Hinduism and the Middle Eastern religions of Judaism, Christianity, and Islam.

Modern iterations of the library as educator may be observed in the adult education movement of the early twentieth century, which valued self-education as a tool of economic opportunity, as well as in twenty-first century literacy programs. The educative power of the library has tended to find its richest expressions in the great universities established in Europe in the Middle Ages and which—along with newer universities in the United States—have been transformed into the multicampus universities of today. These institutions, in concert with great national and private research libraries, have become part and parcel of intellectual and scientific progress—in the most literate nations—in the discovery and production of new knowledge, that most precious of commodities that marks human striving for a better world. The universities are also part of larger public and private educational systems, having been constructed on the foundation of K–12 (kindergarten through 12th grade) schooling wherein the school librarian through the reading and telling of stories, or equally often the public librarian, provides children with their earliest strategic impressions of the learning potential of books and libraries. The special role of the public library remains that of accommodating a wide range of reading tastes, serving citizens with a variety of community programs, welcoming readers in ways for which schools and universities are less well structured, and protecting the freedom to read.

The Ideology of Reading

The desire to use the collections and services of a library or to pursue the practice of library work or research and teaching in library and information science is a desire that, hypothetically at least, is rooted in the desire to read. Biographies and autobiographies in all fields of endeavor, including librarianship, provide abundant testimony to

early transformational moments when individuals were mentored by a library worker, or when they spent countless hours browsing library collections and reading books.

Michael Harris defines the ideology of reading as a consensus about the value of reading and the widespread dissemination of books and writing to the growth and progress of a nation or a community. This ideology becomes clear in three particular constructs. The first of these is control, the idea that books and libraries symbolize power exercised by elites in order to support their values and interests. Social control may function to cultivate compliance among lower classes in order to maintain the political *status quo* and avoid civil unrest. Not uniformly shared among library historians, this view likely represents the minority perspective contrasted with the more widely appreciated opinion of the public library as an expression of democratic impulses. A second category is the library as commodity, that it is integral to an elaborate enterprise that incorporates the related work of authors, publishers, marketing specialists, booksellers, and libraries. Partners in the enterprise thrive in those societies with economies diverse enough to support them.

A final category of the library is that of memory. A nation or a municipality develops the capacity to reflect on its progress and to examine and revise its history but also to perform these tasks in settings that are monumental, places that are iconic enough to remind citizens of their cultural and intellectual maturity.^[21] Thus millions of words organized into the reading matter of civilizations, confirming and promoting human progress, make up the multitude of stories that constitute the large narrative of the library, and they become essential to the high aspirations of individuals and groups, of families and communities, of movements and nations, of actions and ideas.

ACKNOWLEDGMENT

The authors acknowledge with admiration and gratitude the wise counsel and moral support of Donald G. Davis, Jr.

History of Museums

John Edward Simmons

Museologica, Bellefonte, Pennsylvania, U.S.A.

Abstract

Making collections of objects is a universal human practice. Collections were made long before there were museums. The concept of the museum was developed from the association of objects and learning at the Temple of The Muses of ancient Alexandria. Museums have evolved from the private Renaissance cabinets of curiosities, which were open only to a few, into modern institutions with primarily educational functions that both reflect and shape human society.

INTRODUCTION

When James Smithson (ca. 1765–1829) left his fortune to the U.S. government, he stipulated that it be used for “the increase and diffusion of knowledge.”^[1] After debating using the gift to establish a library or a university, Congress instead decided that knowledge could best be increased and diffused in the new republic by creating a public museum. The Smithsonian Institution, established in 1846, now includes 19 museums, 9 research centers, and a zoological park.^[2]

Museums developed in response to the human need to understand the world by using collections of objects—abstractions of the real world^[3]—to make sense of the chaos around them. The collecting and ordering of things is a universal human trait that takes different forms in a diverse array of human cultures.^[4] The earliest evidence of collecting is utilitarian objects and grave goods that were part of the material culture of the earliest humans.^[2] One writer has suggested that the making and keeping of collections stems from “the human propensity to inquire and acquire” and the “twin concepts of preservation and interpretation.”^[5]

Collections are distinguished from random assemblages of objects by the presence of order (the recognition of relationships among the objects). All collections have order even if it is an order that is comprehensible only to the collector. Collections are made for a purpose, while assemblages occur by accident.^[6] What distinguishes the objects in a collection from other objects is that objects in a collection are musealized—that is, they have been removed from their original natural or cultural environment to become part of the collection.^[7,8] In the process of being musealized, objects acquire new meanings and they continue to acquire new meanings as long as they are part of a collection. The history of museums is, in effect, the history of the collection and classification of objects.

COLLECTING IN HISTORY

Collections have a longer history than do museums. Collecting began with the earliest human societies,^[2] and there were established collecting traditions in Africa, Arabia, and Asia long before collecting developed in Europe.^[9] Ancient collections were assembled for a variety of purposes, including for prestige, as economic hoards, and to promote group loyalty. One of the oldest documented collections dates from ca. 530 BCE in the ancient Sumarian city of Uruk, located in present-day Iraq, about 120 miles north of Basra.^[5,10] Excavations of a temple site there by C.L. Woolley and his colleagues in the early 1900s unearthed a collection of antiquities dating back to 2000–2500 BCE that included a boundary stone, a mace head, fragments of a statue, a clay foundation cone, and clay tablets. The objects were documented by inscriptions on a clay drum cylinder on which a scribe had recorded that they were “found in the ruins of Ur, the work of Bur-Sin, King of Ur, which while searching for the ground plan [of the temple] the governor of Ur found, and I saw and wrote out, for the marvel of beholders.”^[11]

By the third millennium BCE, there were extensive collections in the Sumarian state archives at Ebla, and by the second millennium in Mesopotamia, collections of old inscriptions were being used to teach scribes how to make records. During the Shang dynasty in China (ca. 1600–1025 BCE), gold and bronze artifacts were collected; by the time of the Tang dynasty (CE 618–907), collecting had become very popular among the ruling elite.^[10] In what is now Iraq, Nebuchadnezzar (605–562 BCE) acquired a large private collection that included antiquities and natural history specimens, and Nabonidus (555–539 BCE) of Babylonia kept collections of antiquities and natural history objects.^[5] Tuthmosis III (1504–1450 BCE) of Egypt had an extensive collection of art, antiquities, flora, and fauna from Asia.^[5] In an Egyptian tomb, a fossil sea urchin from the Eocene was found that was inscribed in

hieroglyphs with the date, name of the collector, and locality where it was collected.^[12,13] Art collecting was an ancient Greek custom, associated with the exhibition of paintings and sculptures in the entrance peristyles and porches of temples^[14–16] in an area known as the pinakothekē or picture gallery. Wealthy Roman citizens collected paintings and objects that were considered to be “unusual and curious.”^[5] Several private collections of exotic sea shells have been found during the excavation of the ruins of Pompey, and collections of fossils have been found in ancient Greek and Roman cities, as well as collections of precious stones, decorative objects, and antiquities.^[9,12] The oldest continuously functioning museum in the world is probably the Shōsōin at the Tōdai Temple in Nara, Japan, founded in the eighth century, which still exhibits secular and sacred artworks.^[14]

THE MUSEUM CONCEPT

Both the modern concept of a museum as a place where learning and objects are associated and the source of the word museum (from the Greek *mouseion*, or “seat of the muses”) originated in antiquity at a philosophical institution called the Temple of the Muses (a reference to the Greek sister-goddesses).^[17] The temple was considered to be “a place of contemplation” in which learning and objects were combined.^[9,18,19] The Temple of the Muses was founded in the third-century BCE in the city of Alexandria by Ptolemy Soter (305–283 BCE). Objects of art and natural history were collected at the institution, and many learned scholars worked there, including Euclid and Heraclitus.^[20] The Temple of the Muses had the largest library in the ancient world, lecture halls, gardens, and dormitories for scholars. It continued to flourish under Ptolemy Philadelphus (285–246 BCE). The temple and its collections were ultimately destroyed, probably in a fire that swept Alexandria.^[5]

The concept of preservation is closely related to the concept of collecting because for collections to be useful the objects in them have to endure. Some objects are much more durable than others, thus the material the objects were composed of determined, in large part, what went into early collections. For example, preserving organic matter is particularly difficult—animal skins, plant-based materials, leather, and textiles require much more care to preserve so that they can be passed on from one generation to the next than do ceramics or stone.^[21] Dehydration (mummification) is the oldest known method of intentional preservation of organic materials. Mummies were made of both humans and other animals on purpose (by removing the soft tissues most prone to deterioration, dehydrating the flesh with salts, wrapping the body in textiles or skins, and treating the bundle with oils and resins to keep pests away) at least 8000 years ago in Peru and at least 5000 years ago in Egypt.^[22,23] In classical Greece, the tradition of donating

objects to treasuries at public sanctuaries led to attempts to prevent deterioration by such means as coating metal objects in pitch and preventing dehydration of ivory and wood by the use of oils.^[14,24,25]

For collections to be useful in helping understand the world, the objects in them have to be organized or classified. Much like collecting, the organization of objects also stems from an innate human impulse.^[26] The organization of objects is based on real or perceived similarities and patterns. In order to sort out objects, people must be able to distinguish them, hence the collection and the organization of collections is closely linked to the establishment of naming systems (taxonomies). In many cultural traditions, establishing a taxonomic system is part of the creation story, as in the Judeo-Christian-Islamic creation myth in which one of the first tasks of the first human is to name the animals.^[2]

The first useful and enduring taxonomy of animals was proposed by Aristotle (384–322 BCE), and for plants, by a student of Aristotle named Theophrastus (ca. 372–287 BCE).^[27] Aristotle had been a student of Plato in Athens and later moved to Macedonia to become the tutor for the young prince Alexander, the future conqueror of the world.^[19] Aristotle arranged all the known animals—about 540 species—in a gradual progression or *scala natura* based on what he perceived to be their degree of perfection, with invertebrates at the lowest part of the scale and humans at the highest.^[28] Aristotle’s knowledge of animals was based mostly on his own observations and dissections, but he made a few curious mistakes that reflected dominant cultural traditions (e.g., while noting that the internal organs of a dog and a lion were very similar, he also repeated the ancient folklore that a lion has only one bone in its neck; and although familiar with human anatomy, he thought that the heart was the seat of the soul and that the only functions of the brain were to cool the blood and produce mucous).^[29] Much of Aristotle’s knowledge of non-Mediterranean species was based on specimens or descriptions sent back to Macedonia by Alexander the Great. For example, Aristotle’s account of elephants and their natural history in *Historia Animalium* was derived from eyewitness descriptions^[27] and possibly from direct examination of bones or pieces of skin (the first elephants that Alexander saw were those used by Darius at the Battle of Gaugamela in 331 BCE).^[30] Aristotle’s *scala natura* concept had a profound influence on Western perceptions of nature and cultures for the next two thousand years, which was expressed in the way specimens, artifacts, and other objects were arranged in collections.^[31]

EVOLUTION OF THE MUSEUM CONCEPT

Between approximately 900 and 1200 CE, a great intellectual awakening took place in the Middle East, including the translation of many Greek texts into Arabic and the

development of extensive archives and collections of artistic works/>>.^[32] At this time, an Arabic collecting tradition was formalized by the Islamic concept of property given for the public good and the donation of objects, similar to the deposition of objects in the treasuries of Greek temples.^[5] The work of the Islamic scholars did not reach Europe until the twelfth or thirteenth centuries when the Arabic texts and the Arabic translations of Greek texts were translated into Latin. These translations initiated an admiration for the works of classical antiquity in Europe, which in turn spurred the growth of private collections and encouraged several popes, princes, and other wealthy citizens to fund the excavations of classical sites, particularly between about 1450 and 1550.^[2] This is the period when the first *cabinets of curiosities* (also called *Kunst-* or *Wunderkammern*) appeared in Europe.^[33]

Pre-Renaissance collecting in Europe was largely confined to collections acquired by churches, which were the centers of intellectual life.^[14,33] Church collections included not just sacred art and religious objects, but also rare and unusual things such as the bones of giants, griffin's eggs, classical statuary, and artifacts of historical note.^[9,14] Some of the objects in these collections were quite fantastic—the Cathedral in Milan (Italy) claimed a hair from the beard of Noah; the Cathedral of Halberstadt (Germany) exhibited a bone from the whale that swallowed Jonah; the Cathedral in Brunswick boasted a griffin's claw, personally brought back from Palestine by Duke Henry the Lion.^[9] From surviving collections, it is now known that goat and antelope horns were often thought to be griffin's claws, fossil sharks teeth were thought to be snake tongues, and elephant bones were assumed to be the bones of giants. Such objects were accepted in the church collections not just because they were unusual, but also because they were thought to be useful in understanding the world. For example, at a time when very few Europeans had seen an ostrich or even an illustration of an ostrich, it was easy to believe that ostrich eggs were the eggs of griffins. However, ostriches were also mentioned in the Biblical book of Job, where it was recorded that the ostrich sometimes forgets its eggs, but when it finds them again, the bird cherishes them all the more, thus ostrich eggs were symbolic of God's love for repentant humans.^[9]

MUSEUMS, CLASSIFICATION SYSTEMS, AND SOCIETY

As collections began to be assembled in private cabinets of curiosities in the 1400s, classification schemes were needed to give order to the objects.^[34] Initially, objects were simply separated into *mirabilia* (finite marvels) and *miracula* (infinite or divine marvels), or into *artificialia* and *naturalia* (Table 1). As the collections grew larger and more complex, new categories were added, such as *antiquitas* for objects of historical import.^[33] The first cabinets of curiosities were small cabinets filled with

Table 1 Some museum collection classification schemes.

Date	Categories	Source of classification
Early 1400s	Mirabilia (finite marvels) Miracula (infinite or divine marvels)	Wunderkammers, Kunstkammers, Cabinets of Curiosities
Mid 1400s	Artificialia Naturalia	
Late 1400s	Artificialia Naturalia Antiquitas	
1565	Material glorifying the founder Handcrafts from antiquity Natural specimens Technical and cultural objects Paintings and sacred objects	Samuel von Quicchebert
1679	Objects from mines Growing things Animals Works of art	Jan Swammerdam
1727	Naturalia Artificialia Curiosa	Caspar Neikelius
1714	Natural history Things sacred and superstitious Artificial rarities Apparatus (philosophical, mathematical, anatomical, surgical, and chemical) Coins and medals	Michael Bernhard Valentini
1759	Manuscripts, medals, and coins Natural and artificial productions Printed books	British Museum
1814	Manuscripts, medals, and coins Natural and artificial productions Printed books Antiquities and art	British Museum
1823	Ancient relics Arms Dresses and implements of half-civilized nations Rarities (gifts, memorials, amulets, curious works of art) Pictures Books and manuscripts Zoological specimens	Ashmolean Museum at Oxford

treasurers of nature and interesting works of art, but the term rapidly evolved to refer to whole rooms filled with treasures. Francis Bacon (1561–1626) described a typical cabinet of curiosities as containing “. . .whatsoever the hand

of man by exquisite art or engine has made rare in stuff, form, or motion; whatsoever singularity, chance and the shuffle of things hath produced; whatsoever Nature has wrought in things that want life and may be kept.”^[35] The cabinets contained such things as unicorn horns (narwhale tusks), giant’s bones (usually the bones of elephants or mastodons), Egyptian mummies, and snake’s tongues (fossil shark teeth), as well as relics of saints, religious and secular classical art, statuary, and the occasional object from Asia or Africa.^[9] Along with the cabinets of curiosities came a new “...veneration of the rare, the unusual, the wonderful and the miraculous...”^[36] The collections in these cabinets confirmed the existence of a divine being and demonstrated to their collectors that there was a divine order in nature, thus “One of the true *raison d’être* behind the growth of cabinets of curiosities was a restless desire to establish a continuity between art and nature. Thus they demonstrate the existence of a supreme unifying principle.”^[33]

In addition to their value as collectables, many of the objects in the cabinets of curiosities were highly prized for their use in the practice of medicine and alchemy, such as healing stones and mummy dust, or because of the power the objects were believed to possess.^[9] Lorenzo the Magnificent (1449–1492), a member of the Medici family of Florence, had a unicorn horn (a narwhale tusk) in his collection, which was particularly valuable as unicorn horns were believed to sweat in the presence of poison.^[9] Lorenzo’s collections included books, intaglios, precious stones, medals, tapestries, Byzantine icons, sculptures, natural history specimens, and paintings (many of which had miraculous properties).^[37] The word *museum* was first used in Europe in the fifteenth century to describe the collection of Lorenzo^[38] in reference to the encyclopedic nature of the collections (the word *museum* made its first appearance in an English work in 1615); the word *gallery* is derived from the name of the long, narrow corridors in the Medici palaces where their treasures were exhibited.^[12] Curiously, the word *collector* was not used until 1582, and then only to refer to a literary compiler.^[39]

The development of the collections in the Medici palace was based on “Wealth, patronage, and the use of the past...” to glorify the family members based on the role of magic and occult cosmology in giving power to objects.^[37] By possessing objects of great power, the Medici family showed that it, too, had great power. The Medici collections were opened to the public at the Uffizi Palace (which had originally housed Florentine administrative offices) in 1582, and ultimately were bequeathed to the state of Tuscany in 1743.^[5]

THE POWER OF OBJECTS AND THE TRANSMISSION OF KNOWLEDGE

A common object in the cabinets of curiosities, including that of Lorenzo the Magnificent, was a snake-stone (Fig. 1),

Fig. 1 A snake-stone or ammonite (a fossil cephalopod from the early Cretaceous, *Pulchella veleziensis*).

Source: Photo by J.E. Simmons.

named for its resemblance to a coiled snake.^[37] Snake-stones were believed to prevent snake bite and to cure both snake bite and rabies. Another name for a snake-stone was an ammonite, derived from its resemblance to the *Cornu Ammonis*, or Ammon’s Horn, a reference to the Egyptian deity who was depicted with the body of a human and the head of a ram with a coiled horn (Alexander the Great had coins struck featuring his profile wearing the Horn of Ammon to affirm his deity).^[12] In Medieval times, fossils were thought to be formed by exhalations, as described by Aristotle (fuliginous exhalations formed fossils, ochre, sulfur, and vermillion, while vaporous exhalations formed metals), or believed to grow in the earth.^[9] Snake-stones were valued in alchemy because they were thought to be formed by the conjunction of two pure salts. Snake-stones are still common in museums and still popular with collectors even though they are now known to be fossil cephalopods about 400–1400 million years old. The snake-stone shown in Fig. 1 was purchased as an example of the oxidation of pyrite in a geological collection stored at too high a relative humidity. These various conceptions of snake-stones—as medical devices, alchemical substances, scientific specimens, collectables, and teaching aids—are all dependent on the concept that underlies why museums grew and flourished from the cabinets of curiosities onward: *objects are perceived to have power*.^[13] The belief in the power of objects greatly influenced what was collected and preserved. For example, “No museum of any repute was considered complete without one or more specimens of unicorn’s horn, an article which was believed to possess wonderful virtues, and was much employed in medicine.... The Grand Inquisitor Torquemada always carried about with him the horn of a unicorn to protect him against poison and assassins,” and mummies were believed to be “endowed with extraordinary virtues.”^[9] Mummy dust was used to stop bleeding, to heal bruises and fractures, and to relieve convulsions. Murray notes

that “although all museums could not attain an entire mummy, nearly every one had one or more fragments,” such as a finger, a foot, or a head.^[9]

Since the sixteenth century, collectors have organized their collections in ways that promote the transmission of knowledge.^[26] Museum classification systems grew more sophisticated when it became possible to print and circulate collection catalogs.^[2] The first museum catalogs were little more than descriptive inventories of collections, but these rapidly evolved into detailed listings of museum contents with illustrations, histories of significant objects, and critiques of the collection.^[40] Ulisse Aldrovandi (1522–1605) went so far with his museum catalog as to also produce a “...*Catalogus virorum qui vistarunt Musaeum nostrum*, in which he categorized his visitors according to their geographical origins and social standing.”^[33]

One of the first printed museum catalogs was prepared by Samuel von Quicchebert (1529–1567), a physician in Antwerp, and published in Munich in 1565.^[41] Quicchebert wrote that a collection should be a systematic classification of the materials of the universe, and he provided guidelines for assembling what he considered to be an ideal cabinet of curiosities. Quicchebert proposed an organization scheme (Table 1) that classified objects into five groups that Pearce has pointed out correlate well with modern museum divisions: material glorifying the founder and handcrafts from antiquity (historic objects); natural specimens (natural history materials); technical and cultural objects (applied art and crafts); and paintings and sacred objects (fine art).^[3] Quicchebert recommended that a museum include a library, workshop, and apothecary shop, and he described his ideal institution as “A theater of the broadest scope, containing authentic materials and precise reproductions of the whole of the universe.”^[33] In the same year that Quicchebert’s catalog was published (1565), Johannes Kentmann (1518–1574) of Torgau published a catalog of his 1600 rock and mineral specimens, organizing the catalog according to the newly published classification of rocks and minerals in *De re metallica* (1556) developed by Georgius Agricola (1494–1555).^[9]

One of the best-known European collections of this time was compiled by Olaus Worm (1588–1654) in Copenhagen beginning in 1620 and described in an extensive catalog, *Museum Wormianum*, published in 1655.^[42] Worm’s catalog included a woodcut depicting the main room of the museum that has been widely reproduced in many publications about museums. The *Wunderkammer* of Jacobz Swammerdam, a Dutch pharmacist, was cataloged by his son, Jan Swammerdam, after the elder Swammerdam died in 1679.^[2] Swammerdam the Younger divided the large and by then famous collection into four categories (Table 1) consisting of objects from mines, growing things, animals, and works of art (which included ethnographic objects). One of the first museum catalogs to be printed in English appeared in 1691, entitled the

“Catalogue of all the chiefest Rarities in the Publick Theater and Anatomie-Hall of the University of Leyden,”^[9] prepared primarily for the use of visitors to the museum. The catalog listings included shoes and sandals from Russia, Siam, and Egypt; the skin of a man dressed as parchment; “A drinking cup [made] of the skull of a Moor killed in the beleaguering of Haerlem”; Chinese paper; Egyptian mummies; a Roman lamp believed to be capable of burning eternally; “an Hand of a Meermaide presented by Prince Mauritz”; and a 100-year-old mushroom.^[9]

The oldest surviving purpose-built museum building was designed by Wilhelm Egkl and constructed in Munich between 1563 and 1567 to exhibit the paintings of Wilhelm IV and Albrecht V.^[38] The building is now known as the Mint (Münzhof) as it housed the Bavarian mint from 1809 to 1983.

Two of the great collectors of the Renaissance were Konrad Gessner (1516–1565) and Ulisse Aldrovandi (1522–1605), both of whom compiled and published detailed, illustrated catalogs of their collections.^[31] Gessner, born in Zurich, wrote *Historia animalium*, a work of 3500 pages in four immense folio volumes in which he arranged all the known animal species according to the *scala natura* scheme proposed by Aristotle. After Gessner died of the plague at the age of 49, his collection was acquired by Felix Potter (1536–1614) and then passed on to the Natural History Museum at Basle where some of the specimens are still extant.^[38] Aldrovandi, who was from Bologna, taught medicine in Padua and Rome while spending his family’s fortune collecting specimens of animals and plants and hiring artists to illustrate them. The Aldrovandi collections are now in the University of Bologna.^[38] About this same time, the first herbarium was made by Luca Ghini (1490–1556) in Padua, Italy, when he invented the practice of pressing and drying plants and then attaching them to paper sheets, called a *hortus siccus* or “dry garden.”^[38,43]

THE MODERN MUSEUM

The modern museum dates to the time when collections began to be made for the specific purpose of exhibiting the objects to the public, but this is not an easy-to-define moment. One of the first public European museums was formed when the Grimani family bequeathed their private collections to the government of Venice between 1523 and 1583.^[38] The Grimani collections are now part of the present-day archeological museum of Venice. Many other such donations of collections and the subsequent creation of public museums followed. During this time, systems and scientific methods were being applied to understand both human culture and nature.^[38] For example, Francis Bacon (1561–1626) argued for the application of inductive empiricism to the cataloging of knowledge, and

Table 2 Nature of museum collections.

Museum type	Collections description
Art	Aesthetic
History	Documentary
Science	Systematic

René Descartes (1596–1650) sought to rationalize science and religion, developments that were reflected in the nature of museum collections (Table 2).^[44]

In England, the Tradescants sought the services of Elias Ashmole (1617–1692) to catalog their own extensive collections, which ultimately became the first public museum in England.^[39] John Tradescant the Elder (ca. 1570–1638) and his son John Tradescant the Younger (1608–1662) collected natural history specimens, precious stones, weapons, coins, carvings, paintings, and medallions from all over the world.^[34] Tradescant the Elder wrote to the Secretary of the Admiralty in 1625 and asked for help in obtaining things “. . . that be Rare or Not knowne to us” as well as “Any thing that Is strang.”^[39] This request came at the same time as the Tradescant collections began to be exhibited to the public at Lambeth.^[38] Ashmole’s catalog of the Tradescant collection was published in 1656 under the title *Musaeum Tradescantianum*. After the elder Tradescant died, the ownership of the collection passed to the younger Tradescant, and after his death Ashmole moved to take over the collection even though the widow, Hester Tradescant, resisted.^[39] Ultimately, after a protracted legal battle, Ashmole gained control over the collection and donated it to Oxford University, where a part of it is still on exhibition as the Ashmolean collection.^[45] The Ashmolean Museum established the pattern for what eventually became the modern university museum. Opened in 1683, the Ashmolean included not only space for exhibition and storage of collections, but also offices for the teaching staff associated with the university.^[46]

Sir Hans Sloane (1660–1753) made the collections that became the core of the British Museum.^[9] Sloane’s collections were encyclopedic in scope.^[39] The catalog of the collections of the Royal Society of London included listings for “A piece of BONE voided by Sir W. Throgmorton with his urine,” “A Weesle Headed Armadillo,” and a piece of “skin from the Buttock of a Rhinoceros.”^[47] Museums had objects like these in their collections largely because “The object of showing such things was that they were expected and that the museum should not seem to be incomplete by their not being there.”^[9] John Henry Parker, the curator of the Ashmolean Museum, wrote in 1871 that “I do not wish to exclude curiosities from [the museum]; they attract people, and when they are brought hither by curiosity, they may stop to learn something better; they may want to know something of the history of the curiosities they have come to see.”^[9]

Museums were numerous enough in Europe after 1700 that a museum object dealer from Hamburg named Caspar Neikeli (a pseudonym for Kaspar Freidrich Jenequel)

published a book called *Museographica* in 1727, considered to be the first museological work.^[48,49] Neikeli provided guidance for acquisitions; addressed problems of classification of the objects in the collection as naturalia, artificialia, and curiosa (Table 1); presented techniques for caring for collections; and suggested putting a table in the middle of each room “. . . where things brought from the repository could be studied.” Neikeli recommended that museum objects be stored in dry conditions and kept out of direct sunlight, and that museums should have an accession book and a general catalog.^[15] Neikeli was the first to articulate the difference between viewing objects clustered in a small room (e.g., as in a cabinet of curiosities) and displayed in a long room (an exhibition hall derived from the *grande sale* of the French medieval chateaux).^[48] As late as 1759, the original organization of the British Museum reflected Neikeli’s divisions of knowledge with its collections divided into three departments: manuscripts, medals, and coins; natural and artificial productions; and printed books (Table 1).

In 1753, David Hultman published his recommendations for museums, writing that a museum building should be made of brick, be longer than it is wide, and have windows facing north.^[9] Despite the appearance of the books by Neikeli and Hultman, collection care in museums at this time was, in general, not terribly good. “. . . William Swainson compared the storerooms [of the British Museum] with the catacombs at Palermo, each of which was apparently opened once a year to determine how much decay had occurred and to deposit fresh material.”^[36]

As museums grew larger and more complex early in the eighteenth century, they began to diverge into specialized institutions such as art, ethnographic, history, military, natural history, and technology museums, based on the characteristics of their collections and the systems of order used to categorize the objects in their collection (Table 3).^[2] For example, natural history collections benefited greatly from the advent of new taxonomic classification systems for plants (in 1735) and animals (in 1758) developed by the Swedish naturalist, Carl Linnaeus (1707–1778).^[50] These efficient, modern classification systems quickly became the principle around which natural history collections were organized and collection growth was directed. An equivalent common universal

Table 3 Generalized systems of order used in museum collections.

Type of museum	Ordering system
Art	Artists’ name, period, medium, genre, school
Natural history	Linnaean taxonomy
Geoscience	Epochs, strata, chemical composition
History	Material, topical class (use), style, Chenhall classification
Anthropology	Material, provenance, cultural association

cataloging taxonomy for human-made objects did not become available until 1978.^[51] By contrast, the Dewey Decimal system for cataloging library materials in 10 major classes appeared in 1876, the Library of Congress system (using 21 classes) was first published in 1897, and the Universal Decimal Classification was published in Europe in 1895.^[2]

Many of the new museums were less encyclopedic and more focused in their collections, such as the first of what are now the Vatican Museums, the Museo Sacro, which opened in Rome in 1756.^[52] A number of museums specializing in art, history, and natural history were founded at this time. The first museum devoted exclusively to art, the Pio Clemente Museum, was opened in 1773 in Rome by Pope Clement XIV (the museum's holdings are now part of the Vatican collections).^[52] Most early European museums started with collections assembled by happenstance, but some were planned more thoroughly. The first modern art museum was the Hermitage in St. Petersburg, Russia, which was established in 1764.^[9] The Czartoryski Museum (Krakow) was founded in 1796 to bring collections from the aristocracy to the general public. In 1779, Christian Von Mechel suggested that the Belvedere Museum in Vienna should be arranged to present "a visible history of art," in a chronological framework.^[48] This was followed by the Altes Museum in Berlin (1830), also designed to provide "a visual history of art from its beginnings."^[5] The Alte Pinakothek in Munich (1836) opened with a chronological exhibit of art by organized by schools, with gallery spaces designed to protect the artwork from fire, dust, and vibration, with north-facing windows, and moderate heat in the winter.^[38]

The first museum in the United States was established in 1773 by the Charleston Library Society, in Charleston, South Carolina.^[53] In 1785, the first public museum in the United States was operated by Charles Willson Peale (1741–1827), initially in his home in Philadelphia.^[54,55] Based on the European concept of a museum, Peale's innovation was his democratic intention to provide instruction and entertainment to all classes of people. Peale's museum included paintings by himself and his sons, taxidermy mounts, fossils, a mastodon skeleton, ethnographic objects, and live animals.^[54] Peale's museum eventually failed when it was confronted with many of the same problems that many museums face today—funding, maintaining audience, and presentations. The Peale collections were dispersed at auction in 1858—of the 1600 bird taxidermy mounts prepared by the Peale family, only 14 are known to exist today.^[55]

A number of significant museums were founded around this time (Table 4). The British Museum was opened to the public in 1759 (with free admission), with its collections of art, anthropology, history, science, and a library, making it a universal institution.^[38] Charles III of Spain brought together works of art and natural history in 1785 as a museum of natural science, which eventually became

Table 4 Founding dates of some significant museums.

Date of founding	Museum
1523	Grimani collections given to Venice and opened to public
1567	Wilhelm IV and Albrecht V collections established in a purpose-built structure (Munich, Germany)
1582	Medici collections opened to the public at Uffizi Palace (bequeathed to Tuscany in 1743)
1620	Museum of Olaus Worm (Copenhagen)
1625	Tradescant collections on public exhibit in England, to become the Ashmolean Museum at Oxford in 1683
1752	Museo Nacional de Ciencias Naturales (Madrid)
1756	Museo Sacro, Rome (now part of the Vatican Museums)
1759	British Museum (London)
1764	Hermitage (St. Petersburg)
1773	Charleston Library Society (Charleston, South Carolina)
	Pio-Clemente Museum (Rome)
1778	The Batavia Society for Art and Science (now the Central Museum of Indonesian Culture, Jakarta)
1784	The Indian Museum (Calcutta)
1785	The Peale Museum (Philadelphia)
1787	The Prado (Madrid)
1791	The Massachusetts Historical Society (library and public exhibition gallery)
1793	Muséum Central des Artes, now the Louvre (Paris)
1796	Czartoryski Museum (Krakow)
1802	National Museum (Pest)
1814	Asiatic Society of Bengal (Calcutta)
1815	Rijksmuseum (Amsterdam)
	National Museum (Rio de Janeiro)
1818	Moravian Museum (Brno)
1822	Picton Academy, the first Canadian museum (Nova Scotia)
1823	Museo del Pais, now Argentine Museum of Natural History (Buenos Aires)
	Raffles Museum and Library, now Singapore National Museum (Singapore)
1824	National Museum of Colombia (Bogotá)
1825	South African Museum (Capetown)
1830	Altes Museum (Berlin)
1836	Alte Pinakothek Museum (Munich)
1837	Ethnology Museum (Leiden)
1838	National Gallery (London)
1841	Nelson Provincial Museum (New Zealand)
1842	Ancanthe Museum (Hobart)
	Wadsworth Atheneum at Harvard University (Cambridge)
1843	National Museum of Canada, now Canadian Museum of Nature (Ottawa)
	Egyptian Museum (Cairo)
1850	Hasbrouck House (Newburgh)

2009	Acropolis Museum (Athens)

the Prado in 1819.^[38] The Louvre opened to the public as the Muséum Central des Artes in Paris in 1793, shortly after the French Revolution, exhibiting royal collections that had previously been unavailable to the public, outside of an occasional special exhibition.^[38] The new French museum grew rapidly as Napoleon appropriated objects for the collections during his European campaigns, but most of this material was later repatriated, after the Congress of Vienna in 1815.^[5,38]

The development of mercantilism, the rise of an affluent merchant class, and the decline of royal patronage systems together led to a greater public interest in the arts beginning early in the eighteenth century.^[5] By the middle of the eighteenth century, the dawning Industrial Revolution sparked public interest in technology and science. At the beginning of the nineteenth century, “the first realization of the role of the museum in contributing to national consciousness arose in Europe. With it came the recognition that the museum was the appropriate institution for the preservation of a nation’s historic heritage.”^[38] Thus came the first big museum “boom” in the second half of the nineteenth century in Europe. So much museum growth occurred during this time that the nineteenth century has been called the Golden Age of Museums in Europe; nearly every country in Western Europe opened a comprehensive museum during this time.^[14]

One influential museum pioneer in the United States was Phineas T. Barnum (1810–1891), who opened a huge public museum called The American Museum in New York after his purchase of the collection of John Scudder (1775–1821).^[56] In his museum, Barnum exhibited more than 600,000 objects,^[1] but finally gave up on museums and went into the circus business after a series of disastrous museum fires. In 1842, Barnum acquired a specimen of “a feejee mermade,” which he put on exhibit with much fanfare in his New York museum, where it tripled revenues.^[57] Once the novelty of the mermaid wore off in New York, he sent it out on tour. Scientists throughout the United States protested the local showings, claiming that the mermaid was an obvious fake, but their protests only served to push ticket sales higher. The mermaid was described in the press as an “ugly dried-up, block-looking, and diminutive specimen about 3 ft long. Its mouth was open, its tail turned over, and its arms thrown up, giving it the appearance of having died in great agony.” The mermaid was made from the torso and head of a monkey sewn onto the body of a fish.^[58]

THE CHANGING ROLE OF MUSEUMS

In the latter part of the nineteenth century, museums were recast as primarily educational institutions as the “new museum idea” took hold—this was the separation of study collections from exhibition collections.^[2] The new museum idea was formally articulated by Sir William Henry Flower

(1831–1899), director of the British Museum, who proposed organizing museums around the dual purposes of research and public education.^[59,60] Until this time, museums had been expected to put all of their collections on display, with the result that exhibit halls were often vast arrays of carefully labeled and arranged objects in ordered cases. Although it has become fashionable to criticize this style of exhibit, it was very popular with visitors who sought out museums to see things that they had never seen before, arranged in a ways that brought made sense the chaos around them. The second half of the nineteenth century was also the time of the first period of major growth in museums, with more than 100 new museums opening in the United Kingdom and at least 50 new museums in Germany,^[5] and many significant museums opening in the Americas (Table 4).

The first ethnology museum opened in Leiden in 1837.^[16] Historic house museums first appeared in the mid-nineteenth century in Europe and the United States, dedicated to preserving buildings because of their significant architecture or association with a significant person or historical event (Fig. 2). The first historic house museum in the United States was Hasbrouck House, founded in 1850 in Newburgh, New York, once the headquarters of General George Washington.^[1]

Open air museums or living museums (Fig. 3), which usually include period architecture (often recreated) and historical re-enactors, were developed in the late nineteenth century in Scandinavia.^[2] The first open air museum was

opened in 1881 near Oslo, Norway, to exhibit the collections of King Oscar II. In 1891, Arthur Hazelius founded the Skansen museum in Stockholm, which became the model for subsequent open air museums around the world.^[2] The first outdoor museums in the United States were the historic environment known as Colonial Williamsburg, established in 1926,^[23,33] and the Henry Ford Greenfield Village museum, which opened in Dearborn, Michigan, in 1928.^[54] The first mobile museum was developed in Liverpool in 1884 to serve school children.^[16]

Natural history museums underwent a major change following the publication of *On the Origin of Species* by Charles Darwin (1809–1882) in 1859.^[2] The fundamental revolution in biology that was triggered by Darwin's theory of evolution by natural selection had far-reaching effects on how specimens were collected, preserved, and exhibited. Prior to Darwin, species were thought to be immutable, so natural history museum collections contained only one or two specimens of each species, and museums exhibited all of their collections in large synoptic displays, grouped according to the prevailing systems of classification.^[2] Darwin's theory demonstrated the importance of studying variation within species, which meant the essentialist or typological natural history collections were no longer very useful for research. In fact, Darwin could not have developed his theory of evolution using just the museum collections of his day because museums did not have sufficient specimens of each species to show the wide degree of variation in nature.^[2]

At the time that the Smithsonian was founded (in 1846), universities were essentially finishing schools; the creation of knowledge was centered in museums, with the result that "... museums made the fruits of their research available to a general public through exhibits, unlike colleges and universities, which were open only to a few."^[61]

There are some significant differences in how museums were established in different regions of the world.^[2] In Europe and Canada, museums were usually established through local or national government agencies, but in the United States most new museum growth was initiated by individual or small group patronage at the local level. In other countries, centralized state museum systems were developed, as in France and the former Soviet Union.^[62]

Although the idea of the modern public museum is essentially European in origin, it was successfully exported to other parts of the world through trade and colonialism.^[38] There were periods of growth in Latin American and Asian museums in the 1800s, and in African museums in the early 1900s.^[62] Many of these colonial-era museums evolved into important national museums (Table 4) such that "the emergence of the nation-state, the public, and the public museum in the late eighteenth century, were intimately bound together,"^[63] particularly in South America and Asia. As independent nations arose from their colonial roots, some museums became important agencies for developing national identification by offering interpretations of their collections that reflected feelings of national ownership (e.g., defined national culture) as well as defined

nationality compared to other nations and cultures.^[63,64] Some of these museums played a significant role in the rejection of colonialism. For example, during the 1970s many Caribbean museums shifted their emphasis from a strong focus on their society's colonial past to present more inclusive cultural and natural histories.^[65]

Although two significant American museums were founded in 1870—the Metropolitan Museum in New York and the Museum of Fine Arts in Boston^[52]—only 4% of museums in the United States were in existence before 1900.^[62] At least 75% of U.S. museums were founded after 1950, and 40% were founded after 1970.^[1]

Further changes in museum development have occurred in the twentieth century. Technological developments during the First World War, such as efficient indoor lighting and the production of large sheets of polished plate glass, have allowed museums to make much larger display cases.^[3] The population shift in many industrialized countries away from urban centers has spawned the development of community museums.^[38] The growth of museums worldwide resulted in the founding of the International Council of Museums (ICOM) in 1946.^[62] Not all institutions recognized as museums today even own collections. The definition used by the Accreditation Committee of the American Alliance of Museums states that a museum is "An organized and permanent nonprofit institution, essentially educational or esthetic in purpose, with professional staff, that owns or uses tangible objects, cares for them and exhibits them to the public on some

regular schedule,” in contrast to the most widely used definition, that of the International Council of Museums, which states that “A museum is a non-profit, permanent institution in the service of society and its development, open to the public, which acquires, conserves, researches, communicates and exhibits the tangible and intangible heritage of humanity and its environment for the purposes of education, study and enjoyment.”^[2]

Two of the newest concepts in museums are ecomuseums and virtual museums.^[66,67] Ecomuseums interpret not just an event, a place, or a culture, but an entire community. Developed by Hugues de Varine in France in 1971, ecomuseums have proven to be popular in parts of Europe, Canada, and much of the developing world. The hundreds of ecomuseums around the world today define themselves by managing heritage in a sustainable environment. In contrast to ecomuseums, virtual museums exist only in cyberspace, although many are usually based on real, physical collections, and show great promise for repatriation of cultural knowledge and a wider sharing of information around the world.^[68]

CONCLUSION

The significance of the role of museums in presenting history and defining culture has been demonstrated by such events as Chinese museums being forced to interpret a particular political agenda or be closed during the Cultural Revolution of the 1960s, and the attempt by some members of the United States Congress to interfere with the curator's presentation of the bombing of Hiroshima in the Smithsonian's Enola Gay exhibit.^[2] Museums in Eastern Europe both expanded under the post-Communist governments and later struggled to survive in a free market economy. More recently, museums in Iraq and the former Yugoslavia have suffered greatly the ravages of warfare.^[2]

History shows that museums have evolved to serve different needs at different times, but have always played a significant role in interpreting nature and culture. Museums have been “. . . the institutions charged with furthering knowledge and creating order . . .”^[61] due to the fact that they “. . . assumed intellectual leadership because they fostered original research through the careful and systematic way they dealt with objects.”^[61] Museums will continue to serve a significant role in society as long as humans remain curious about the world around them.

History of Paper

Sidney E. Berger

Phillips Library, Peabody Essex Museum, Salem, Massachusetts, U.S.A.

Abstract

Centuries before paper was invented, ideas were communicated in various ways other than orally. We know of the paintings on cave walls, and the use of wood, clay, stone, bamboo, wax, silk, palm leaves, and other surfaces. In the West, the immediate predecessors to paper are papyrus and vellum or parchment, the dried skins of animals, which was in use in the West at about the same time as was the earliest papers in the Orient: the second century B.C. But paper has had by far a greater impact on civilization than has any other material ever invented.

INTRODUCTION

Paper is matted fibers.

If that were all there were to it, this entry would not be 9000 words. Paper is an almost magically simple product to make, and it is perhaps—along with printing—one of the most important inventions in history. (Someone suggested that Printing, Paper, and the Alphabet are the “top three” inventions of all times.^[1])

ANTECEDENTS TO PAPER

Centuries before paper was invented, ideas were communicated in various ways other than orally. We know of the paintings on cave walls, and of the use of wood, clay, stone, bamboo, wax, silk, and other surfaces, none of which needs to be rehearsed here. In the West, the immediate predecessors to paper are papyrus and vellum or parchment, the dried skins of animals, which was in use in the West at about the same time as was the earliest papers in the Orient: the second century B.C.^[2]

Papyrus

Papyrus, used as early as 3500 B.C. in Egypt, is a plant of the sedge family, growing in warm moist climates. It can reach heights of 18 feet or more. Much ignorance about papyrus was passed along to us in the West by scholars knowing little or nothing about it, who made pronouncements based on logic rather than on fact. [Witness this rather ludicrous statement: “Papyrus. . . is only one of the predecessors of paper that together are known by the generic term ‘tapa’ and are mostly made from the inner bark of paper mulberry, fig and daphne”; quoted from http://www.paperonline.org/history/3000/3000_frame.html (accessed July 29, 2008). This could hardly be more wrong.] Hence, misstatements abound about papyrus’

manufacture. Only through the efforts of Hassan Ragab were we able to rediscover the secrets of the plant and the writing surface made from it. (His dissertation, *Contribution à l’étude du papyrus (Cyperus papyrus.L) et à sa transformation en support de l’écriture (papyrus des anciens)* (L’Institut National Polytechnique de Grenoble, 1979), was self-published into a book, *Le papyrus* in Cairo in 1980.)

As Alia Hanafi writes:

In 1962, [Hassan Ragab] started the process of re-discovery. But he faced two major obstacles. First, that papyrus was vanished in Egypt, and he had to go to Sudan to re-import the plant. Second, the entire process of papyrus making was maintained as a secret. Therefore, Dr. Ragab read books by Herodotus, Strabo and Theophrastus, but none could describe the process. The only but very vague indication he found in the studies of Pliny the Elder. Nevertheless, this description was so inaccurate that it did not help him in any way. So, he spent the next 4 years researching the method. In July 1966, he produced his first papyrus paper. In 1967, Dr. Ragab founded on a houseboat on the Nile an Institute for the remanufacturing of Papyrus. He started to collect some information from experts, and began his own experiments. Therefore, gradually he found the way to produce sheets in the same quality, the same structure as it was done some thousands years ago [sic].^[3]

One thing to remember is that papyrus is *not* paper. Paper is made from matted fibers—fibers that have been macerated and ground down into pieces of tiny lengths. Papyrus fibers have not been macerated. So to call the material “papyrus paper” as Hanafi does is to misrepresent the sheets.

Another common misperception is that sheets of papyrus are “prepared from the pith of the papyrus plant by cutting it in longitudinal strips, arranging them crosswise in two or three layers, soaking them in water, and pressing them into a homogenous surface.”^[4] This statement has at

least two errors. First, the order of events (laying the strips out and then soaking them) is wrong: the soaking of the strips takes place before the arrangement of the strips. Second, “two or three layers” is incorrect. All one needs is two layers and no literature mentions (and no papyrus sheets evidence) a third layer.

A third error, propagated in the nineteenth century by scholars guessing how the sheets were made, is that one must pound the strips of the stalk. Pounding them would disperse the long fibers and mess up the final leaves. We see such statements as, “The strips may have been soaked in water long enough for decomposition to begin, perhaps increasing adhesion, but this is not certain. While still moist, the two layers are hammered together, mashing the layers into a single sheet.” (This error comes from the error-prone *Wikipedia*.^[5]) The author is following a long tradition of error calling for hammering, smashing, or pounding the layers.

The simple method of making papyrus is as follows:

The stems of the papyrus plant, which are covered with a green “skin” or “bark” and are almost triangular, are filled with a pulpy pith somewhat thicker than but similar in consistency to the pulp of watermelon and with long stringy fibers like those in celery. The stalks are cut down, and then cut into whatever lengths the papyrus maker desires. The green skin is pared off two of the three sides of the stalks, the stalks are sliced into thin strips, and then the last of the green outer “bark” is sliced away.

The strips are then soaked in water to hydrate the fibers. The pith has to be as wet and mushy as possible since it is the blending of this pith within strips lying in different directions that will determine the solidity of the final product.

Various sources talk of how long these strips should be soaked. Soaking for several days, with the water being changed often, will allow for the maximum hydration of the fibers and will allow the pith to break down and become quite soft. The strips are then laid out on a flat surface, first in one direction (slightly overlapping) and then a second layer placed at right angles over the first layer (also overlapping). The strips are then put under great pressure to squeeze out the water and to press the pulp for all of the strips into one solid mass of pulp. Several pressings, each time replacing wet blotting material with dry, pulls the water out of the strips, which are eventually merged into one single leaf of papyrus.

Several leaves can be glued together to make longer and still longer pieces, so that a long text can be written onto a single piece of papyrus. Since the sheet is relatively brittle and will not withstand folding, the standard format of a text on papyrus is either a broadside or a roll (or scroll). The final product is flexible, light and portable, and stable; that is, it has no inherent vice, so it will not deteriorate if it is properly stored and handled. It is generally written on one side only. And while it *is* portable, a long scroll is somewhat unwieldy. Its practicability,

however, and the abundance of such plants made papyrus the most used surface for communication for perhaps 2000 years.

Parchment/Vellum

The word “parchment” has descended from the city Pergamum, an ancient city in Asia Minor, now Bergama, in western Turkey. “Vellum” comes from the French word “velin,” a calf (related to “veal”).

A good deal of confusion about the terms “parchment” and “vellum” has led to their being used practically interchangeably today. Brown and Lovett say, “It is now usually accepted that parchment is sheep or goat skin and vellum calf skin.”^[6] Some writers use the term “vellum” only for calf and “parchment” for any other dried animal skin, including horse, pig, goat, and other mammals. There is even a company making what it calls “parchment” out of snakeskin, the skins of various fish and lizards, and other such creatures. It is dried skin, and it is used in bookbinding and for other artistic products. For all practical purposes, and partly because most people cannot distinguish the skin of one mammal from another (especially that of sheep from that of cows), the two terms have become perfectly interchangeable.

Beverly Boyd claims, “Nowadays... manufacturers of stationary have settled these words for the public by using the term ‘vellum’ to denote a suede-like finish and ‘parchment’ to denote a crisp finish.”^[7] Since that was written (in 1973), the distinction has essentially disappeared.

The following description of the preparation of the skin is necessarily brief, leaving out many details. (For a more thorough treatment see books by Reed.^[8,9]) The butchered animal is flayed, its skin is soaked in lime then stretched on a frame, and the parchment maker, using a lunellum (a moon-shaped knife), pares down the flesh from one side and shaves off the hair from the other. A fine talcum called “pounce” is sometimes burnished onto the skin to smooth it off and act as a mordant, allowing pigments to adhere to the skin. This yields a fine surface, with a hair side and a flesh side. When the signatures of a book made of sheets of parchment were designed, written or drawn on, folded, and gathered, the artists and scribes knew to have hair sides face hair sides and flesh sides to face flesh sides, since the hair sides tended to be somewhat darker than the flesh sides.

The skins were pared down to be quite thin and were thus easy to fold. The modern codex—the book as we know it with leaves written on both sides, folded, and then sewn together through the folds at the inner margins—is the product of book makers of about the second century A.D.

The skins of young animals were generally preferred to those of older ones, but many a large folio attests to the fact that full-grown cows and sheep, goats and pigs were used as well.

A particularly fine kind of vellum, quite thin, strong, white (or just off-white), and lovely, is called “uterine vellum,” presumably because the fetuses were aborted, so that the parchment makers could have such fine skins to work with. Recently, the notion of aborting the fetus has been questioned, especially since an extremely fine skin can be made from a young animal by a skilled craftsman. Using a microscope, an expert may be able to distinguish skin types and follicle patterns to show what animal was used for a particular sheet. But to the naked eye, it is often difficult or impossible to say what animal was used. On the other hand, certain goat skins have a distinct and distinguishable skin.

Naturally, the maker would get out of the skin the largest rectangle he could. But none of the skin would be wasted, for the remainder could be cut into thongs or rendered down to make glue.

Since books were produced one at a time, by hand, the amount of parchment available kept up with the demand for it of the scribes and authors. But certain social forces in the West in the Middle Ages—perhaps the most important of which was the growth of the guild system with a concomitant growth of a middle class—brought about a need for an increasing amount of writing surfaces. Paper in the West was just ripe to be invented.

PAPER

Paper: History

The history of paper is shrouded in mist. We have a few clear facts, like that it was invented in the second century B.C. by the Chinese. We don’t know where in China nor do we know the inventor. We can speculate—as many have done—that some genius observed the work of wasps, who made their nests by macerating the pulp of various trees or shrubs, and whose nests were the inspiration for the making of paper. Whether this is true or not is debatable.

One “fact” that has been foisted on the world for many decades is that paper was invented by a court eunuch, Ts’ai Lun (or Cai Lun, or Lung—his name has several other spellings) under the emperor Ho Ti in 105 A.D. This error has been perpetuated so often and for so long that it has taken on a life of its own, and it is difficult to supplant it with the truth. It is wrong, and for the sake of accuracy and historical correctness, I have made this point emphatically in this long paragraph.

We know that paper existed in China in the second century B.C. One source enigmatically says, “True paper is believed to have originated in China in approximately the 2nd Century A.D., although there is some evidence for it being used before this date”; the source follows this with, “Papermaking is considered to be one of the Four Great Inventions of Ancient China, since the first papermaking process was developed in China during the early

2nd century.” Then this source says: “the discovery of specimens bearing written Chinese characters in 2006 at north-east China’s Gansu province suggest [sic] that paper was in use by the ancient Chinese military more than 100 years before Cai [Lung], in 8 B.C.” And finally, from the same source: “Archeologically, however, true paper without writing has been excavated in China dating to the reign of Emperor Wu of Han from the 2nd century B.C., used for purposes of wrapping or padding protection for delicate bronze mirrors.”^[10]

The Chinese guarded the secret of papermaking for centuries, knowing of the power paper has for transmitting texts. It made its way to Korea and Japan (c. 604 A.D. and 610 A.D., respectively), and then, through Samarkand, to the West in the middle of the twelfth century. By about 1150 the first European papers appear, but how they were made—in a mill or by more primitive methods—no one can determine. We know where the paper came from by what was written on it, so we know that in the last half of the twelfth century paper was being made in Xativa, Spain. And by 1276, the mill in Fabriano, Italy, was at work.

To write a full account of paper’s manufacture in the East and the West would take several volumes. In the short space of an encyclopedia entry, only the most superficial information can be imparted. Even when the information may seem minutely detailed, it is really only scratching the surface since the variety of methods, materials, machinery, and practices is measureless.

Manufacture—Asian Methods

Over the centuries, from its earliest practice in China to today, methods of making paper by hand in Asia have evolved tremendously in some respects and have remained the same in others. This brief discussion will look at only one form of Asian papermaking, the so-called Nagashizuki method, since the other (the Tamezuki method) is similar to that of making paper by hand in the West.

To make paper using the Nagashizuki method, the craftsperson must harvest the fibers. Traditionally, the three basic fibers for making paper are kozo, mitsumata, and gampi, the first being the most common. Kozo is *Broussonetia papyrifera*, the Paper Mulberry, common to many cultures throughout the world.

Because the Japanese have become the most prolific and imaginative, creative and artistic papermakers in history, and because they have been practicing the craft for more than 1400 years, this entry uses the Japanese terminology. Papermaking in China over the centuries and even today is light years behind that in Japan.

Though the process of harvesting and preparing the bark is more complicated than this brief discussion reveals, the basic process is described here.

The plant is harvested in the winter once the leaves have fallen off. The stems are cut into pieces about 4 in. long and are cooked until the outer bark is soft and can be scraped off. This outer bark is tied into bundles and dried. They are stored until they are ready to be made into paper in the spring. When it is time to make the paper, the strips are rehydrated until they are soft. They are crushed in running water with the papermakers' feet. The crushing removes the dark outer layer. This is followed by the careful paring and scraping off of the green middle layer, which adheres to the white inner bark. The long white strips of bark are then dried again until the actual papermaking begins.

The bark is then rinsed, removing the last remaining dark or green bark, and is then cooked in an alkaline solution (usually wood ash or caustic soda). After the cooking, the strips are cooled and the scum on the top of the pot is skimmed off. The strips of fibers are now soft; they are lain onto a board and hit with a stick, with automatic stampers, or in a beater—a machine that slices or grinds up the fibers.

When the fibers are all macerated or cut to the right length (the proper length differs with the different kinds of paper to be made), they are floated in water that has a formation aid in it. The formation aid, called *tororo aoi*, is a slimy gelatinous substance made from the roots of the hibiscus plant. It is called a "formation aid" because it helps the fibers form into a sheet by allowing them to be distributed evenly on the surface of the paper mold.

The mold is dipped into the vat containing the fibers, and a small amount of water and fibers are slid over the mold's surface. This action is done several times until the papermaker has the sheet to the desired thickness.

The mold is in two parts, a *su* and a *geta* (or *keta*). The *geta* is the frame on which the *su* (the screen) sits. Once most of the water has dripped through the *su*, the fibers now distributed on the *su* are matted into a sheet of paper. The flexible *su*, made of thin strips of bamboo, detaches from the *geta* and is taken to a stack of recently made sheets, onto which the fresh sheet is lain. When the *su* peels away, the newly made sheet transfers onto the stack of other sheets. The laying down of the *su* must be done from one long edge, while all the strips of bamboo are "rolled" over the stack of sheets beneath it, so that no air bubbles form under the new sheet.

When the stack of sheets is "complete," the papermaker presses it to squeeze out the water and then dries the sheets in various ways. One common way was to peel a sheet off the pile, brush it onto a tall wooden board along with several other sheets (on both sides of the board) and set the board out into the sun to dry. This also whitens the sheets. A more modern method has the papermaker brushing the wet sheet onto the surface of a metal drum that has been heated. This dries the sheet rather quickly. Both methods leave fine brush strokes on the sheet, and the final product has a board (or drum) side and a brush

side. This accounts for the different feel of the two sides of many pieces of *Washi* (handmade Japanese paper).

Manufacture—Western Methods

The method of making paper in the West has many features of that in the Orient, but with a good number of differences. In fact, the *Tamezuki* style of papermaking in Japan may well come from the Western version of the craft.

To begin with, the fibers in the West were different: there was no *kozo*, *mitsumata*, or *gampi*. In the West, linen and cotton were used. Further, since there was no bamboo, and since metallurgy was well advanced in the West, the paper molds used wires stretched along the long measure of the mold. And finally, since there was no *tororo aoi* in the West, papermakers developed a method of sheet formation that allowed for only a single dipping of the mold into the vat and that did not allow the sheets to be couched (transferred from the mold) onto previously couched sheets. The sheets had to be couched onto woven woolen felts, which pulled the sheets from the mold.

Before the fibers were macerated, they were usually retted—that is, soaked in a tub until the natural action of bacteria caused the fibers to begin to break down. This is sometimes called "bacterial pulping," though the actual pulping, the final maceration, was a mechanical process.

Macerating the fibers was originally done with stamping mills, essentially large mortars and pestles, the latter driven by water or, in the Netherlands, by wind. Wet pulp was placed into the cups of the mortars, and the pestles, driven up and down, pounded the fibers, beating them into little pieces. In the last quarter of the seventeenth century, the Dutch invented the Hollander beater, a machine consisting of a large oval tub divided partly down the middle, forming a sluice around which the water containing the pulp was forced by a large rotating cylinder on the surface of which were blades running parallel to the width of the cylinder. The rotating cylinder forced the pulp under it, and the blades ground and cut the fibers against a bedplate, breaking them down to the desired length.

The wooden mold—four pieces of wood made sturdy and rigid by having supports affixed across the short measure—had metal wires stretched lengthwise across it. The wires were sewn down with chain stitches along the length of each support. The vatman, scooping up the fibers from the tub onto the mold's surface, shook the mold to distribute the fibers evenly over the wires. The fibers settled evenly over the surface except where the chain stitches ran along the supports, at which points the fibers fell more thinly since the chain stitches were above the rest of the surface of the wires. Since the fibers were more thinly distributed where the chain stitches were, when the sheet was held up to the light, more light would shine through the sheet where it was thinner. These so-called "chain

lines” distinguished the handmade papers of the day. Holding a sheet of such paper up to the light, the viewer could see the wire lines going horizontally along the long measure of the sheet and chain lines, separated by a half inch or an inch, going in the other direction.

Also, when the sheet was pressed onto the felt, the supports beneath the wires pressed the fibers above them densely, so when a piece of laid paper was held up to the light, the densely packed fibers would create a dark area around the chain lines, like shadows. What one would see in this so-called “antique laid paper” were the wire lines and chain lines, with shadows around the chain lines.

To avoid the appearance of these shadows, mold makers stretched a second layer of wires across the long measure of the mold, a fraction of an inch above the first layer of wires. Now when the sheet was pressed onto the felt, the supports did not exert any pressure where the chain lines were, so no shadow was formed along them. This new mold created “modern laid paper,” sheets showing the wire lines and chain lines, but no shadows around the chain lines.

After dipping the mold into the vat and distributing the fibers over its surface, the vatman would give the mold to a coucher or layman, who couched the sheet (pressed the mold containing the wet sheet to the felt, transferring the sheet to the felt). (The words are pronounced /koocher/ and /koocht/.) The newly formed sheet would be covered by another felt, and another sheet would be couched upon that, and so forth, until there was a large stack consisting of sheets interleaved with felts. This was called a “post.”

The post was pressed in a large machine and much of the water would be squeezed out. In the vat, the percentage of water to fiber was about 96% to 4%. After the first pressing, the percentage was more like 90% fiber and 10% water. The felts were then removed and the remaining “white post” was pressed a second time. After this second pressing, the sheets could then be removed from the post and hung (or laid out in spurs of five or six sheets) to dry.

The mold was flat, of course, and if it were used by itself, the fibers and water from the vat would run off the edges when it was dipped into the vat. To keep the fibers and water on the surface of the mold while the water dripped away through the wires, a deckle, a rectangular frame, was placed over the mold. Fibers would adhere to the inner edges of this deckle or they would slide under the deckle, forming slightly uneven edges on the sheet—called “deckle edges” or “deckled edges.”

As Allan Stevenson has shown, a typical commercial hand mold was composed of two molds and one deckle. While the vatman was dipping out a sheet from the vat, the coucher (also called the “layman”) was couching another sheet onto a felt from the second mold. When he was done and the sheet had been removed from his mold and deposited onto the post, he would exchange his now-empty mold for the one the vatman had just lifted out of the vat.

The vatman would hand off the mold with the newly formed sheet on it and take the empty mold to begin the process again. If the molds had watermarks, the maker of the molds would try to get the watermarks to look identical and be placed in exactly the same position on the two molds, but that was not always the case, and sometimes we can see variations in watermarks or in their placement on sheets made at the same time by the same makers.^[11]

Sheets made with only water and fiber are called “waterleaf.” The tiny fibers have infinitesimal air pockets around the matted fibers. These pockets, through capillary action, would draw in ink, which could feather out on a sheet as does fountain pen ink on a modern newspaper. The sheets, therefore, needed to be sized, infusing a glue (usually an animal-based glue) into the sheet. The dried sheets would be soaked in the sizing bath, taking the glue in, filling all the tiny air pockets, and preventing inks from feathering out.

It was possible to size the paper by putting the sizing into the vat during the initial sheet formation, but the result would have been pressing the sized sheets onto the felts, imparting the glue to the felts. This would have necessitated a thorough washing of the felts. More common was sizing the papers in a special bath, after the initial drying of the sheets. Hence, there are two kinds of processes: vat sizing and tub sizing, the latter much more common than the former.

The sizing essentially glues all the fibers together, bonding them to one another. Hence the term “bond paper,” which merely designates sized paper, as opposed to waterleaf.

Sheets thus made would be pressed again, and then often calendered—that is, run through a calendering press consisting of two smooth cylinders that put the sheets under great pressure, smoothing off the surfaces. The cylinders could be heated up, so there were hot-pressed and cold-pressed sheets.

In the middle of the eighteenth century, John Baskerville designed a new typeface with fine serifs. If during printing the serif landed exactly on a chain line, where the paper was thin, it may not print perfectly. Baskerville wished to have a smoother, even distribution of fibers in his printing papers. He, or perhaps the famous papermaker James Whatman, devised a mold consisting of wires pulled left to right and also top to bottom, woven together. The result was a sheet formed on a smooth screen, showing no wire lines or chain lines. This paper is called “wove,” not that the fibers are woven, but that the screen from which the paper was made was woven. On the manufacture of wove paper see Hunter.^[12]

Hence, paper can be categorized in several ways: by fiber distribution (modern laid, antique laid, or wove); by content (sized or unsized; and vat sized or tub sized); by surface (calendered or uncalendered; and hot-pressed or cold-pressed papers); and then by other features (colored or not; trimmed or not; watermarked or not; and so forth).

With the invention of wove paper made from a screen, papermakers were no longer forced to use hand molds. The laid wires on the hand mold needed to be held in place by the frame of the mold itself. But a woven screen could be “freestanding.” It was only a matter of time before a clever inventor could take a screen, make a huge loop out of it, and attach one end to the other in a loop. This led to the mechanization of papermaking.

Frenchman Nicholas-Louis Robert is generally given credit for the invention of a papermaking machine—in 1798. The formal patent is recorded on January 18, 1799.^[13] As Hunter explains, Robert quarreled with his backers, sold and then reacquired the patent, and unsuccessfully tried to get a commercial-level machine built in France. He eventually turned to his contact in England, papermaker John Gamble, who interested Henry and Sealy Fourdrinier, stationers, in the machine. They hired Bryan Donkin, a brilliant engineer, who created his own version of the papermaking machine, based on Robert’s patented plans, and on June 23, 1801, the English patent was issued.^[14] To this day, all papermaking machines are called Fourdriniers.

A cylinder machine was invented by English papermaker John Dickinson in 1809, and a similar machine was created by Thomas Gilpin in the United States, in 1817, the first papermaking machine in this country.^[15]

Eventually, the Fourdriniers got to be quite long, containing rollers for drying, embossing, calendering, and otherwise treating papers, along with parts of the machine that added sizing, color, and other modifications to the basic sheet. One such modification was a watermark, created near the very beginning of the papermaking process, before the fibers had fully settled onto the screen. A large roll, called a “dandy roll,” containing the pattern for the watermark disrupted the fibers as they were settling, thinning out the sheet at the point where the dandy roll “landed in” the settling fibers. So lovely watermarks are not necessarily a sign of a handmade sheet.

Similarly, a handmade piece of paper has four deckles around it; such a treatment can be put into a machine-made sheet. And a pattern of chain lines and wire lines can be imparted to the sheet by a dandy roll, so laid paper—which was once purely a handmade product—can also be machine made. Sometimes distinguishing between a handmade and a machine-made sheet can be difficult (but see below under “Grain.”)

PAPER FIBERS

For several centuries in the West (say, from the middle of the twelfth century until the middle of the nineteenth century), the supply of rags was sufficient to satisfy the world’s paper needs. By the second half of the nineteenth century, however, it was clear that another source of fiber was needed. As early as the late eighteenth century,

experiments were being done with straw and certain kinds of wood.

Matthias Koops in England was making paper from straw as early as 1800; and straw was experimented with for decades in the trade. Many other fibers were tried. In fact, since paper is matted fibers, just about any fiber will do. Even synthetic fibers have been used in papermaking. Witness Tyvek®, a synthetic olefin plastic, that makes sturdy, almost untearable paper.

In the last 30 years or so, many hand papermakers have experimented with papermaking by using seriously non-traditional fibers, like vegetables, plants of all kinds, many species of cactus and succulents, and many more unusual materials. They all produce paper of various qualities, and most of them are mere curiosities, not useful for printing or bookbinding.

By the third-quarter of the nineteenth century, wood pulp was adopted as the preferred fiber. It had been experimented with as early as 1765 by Dr. Jacob Christian Schäffer in Germany.^[16] (See the book by Hunter for a more detailed treatment of the use of wood fibers in papermaking.) As Hunter points out, “the first ground-wood pulp produced commercially on this continent was the output of a machine based on the patents of Heinrich Voelter.” “In 1867, Albrecht Pagenstecher founded at Curtisville (now Interlaken) near Stockbridge, Massachusetts, the first ground-wood pulp mill in the United States.”^[17]

Because wood pulp is much more difficult to macerate than hemp or cotton, methods were created to break down the pulp chemically, using sulfuric and other acids. The old method, using sticks, stamping mills, or Hollander beaters, was a mechanical way to prepare the fibers. The new method was chemical; and today we make a distinction between mechanical pulp and chemical pulp.

If the pulp is allowed to soak (or to be cooked) in acids, and then the acids are not sufficiently washed out of the fibers before the paper is made, the acid remains in the sheets. The aim of using chemicals to break down the fibers is to “break down, the chemical structure of the lignin and render it soluble in the chemical liquor so that it may be washed from the cellulose fibers. Because lignin holds the plant cells together, chemical pulping frees the fibers and makes pulp.”^[18] Conservators call the residual acids in the fibers “inherent vice”: a deteriorating material inherent in the papers themselves; they will cause the pulp to break down, the acids attacking the fibers, from within. Paper from the third quarter of the nineteenth century on (and especially commercially made paper) was likely to be made from chemical pulp, and thus millions upon millions of books and documents using this paper will have browned and become brittle if not deacidified. But by the time the deterioration is noticed, the paper has already gotten brown, and the damage is done.

If the lignin remains in the paper, the paper will be acidic. Papermakers can remove the lignin and can also

add buffers like calcium carbonate or magnesium carbonate, so the paper has an alkaline reserve to make it lignin free and acid free. It took a law (Public Law 101-423), signed by President George Bush in October 1990, to require all government printing to be done on acid-free archival paper. Called The Permanent Paper Law, it encouraged the use of acid-free permanent papers for all government documents.

WATERMARKS

One feature of paper that has been a great help to historians and other scholars is whether the paper is watermarked or not. When one holds sheet up to the light, any area that is thinner—that is, an area that has fewer fibers than the areas around it—will show light through the paper. To make the paper thinner at any give point or points, the papermaker affixes something to the surface of the mold that forces the fibers to fall more thinly there than elsewhere on the mold. If a wire in the shape of the letter “R” were sewn or soldered to the surface of the mold, the fibers would fall thinly over it, and the result would be a watermark in the shape of that letter.

Papermakers often identified themselves in simple or elaborate watermarks, sometimes putting the date into the watermark along with their logo. Often a second mark, called a “countermark,” would be put into a sheet, so the final sheet would show a watermark of, say, an animal, a building, a flower, or some other decorative element, along with a countermark of the name of the firm or of the party commissioning the paper.

The word “watermark” is a misnomer since water has little to do with the creation of watermarks.

Watermarks can be produced in several ways, but the key is that the fibers are more thinly (or thickly) distributed where the watermark is than they are in the rest of the sheet. For instance, on a hand-mold, the papermaker can fashion a letter, word, or number out of thin wire and sew or solder it to the surface of the mold. When the fibers fall onto the surface of the mold during the papermaking process, they will fall more thinly where the wire watermark sticks up above the surface. Note that this can be done on any kind of paper mold, antique laid, modern laid, or wove. Also note that the wires themselves are called a “watermark,” and so is the resultant pattern seen in the back-lighted sheet.

A second kind of watermark is done in wove paper only. A male and female die with a pattern in it is used. The wove screen is heated to make the metal malleable, and it is then pressed between the two faces of the die, which contains the pattern for the watermark. The result can be a standard watermark, where a part of the woven screen is embossed (raised in relief), making the fibers fall more thinly where the screen is raised,

and thus creating a watermark in the paper. But the screen can also be de-bossed, that is, pressed inward so that more fibers fall into the groove. The resultant sheet is thicker where more fibers have fallen, and therefore less light shines through the sheet where the watermark is. The notion that a watermark is always revealed in light is thus not strictly correct, for in this case, the mark consists of darker areas of the paper.

Many such male-and-female-die watermarks have both embossed and de-bossed levels in them, so the watermark they produce can have the light that comes through the rest of the sheet, a lighter area for part of the watermark, and a darker area for the other part. This is called a three-plane watermark.

Another kind of mark is also made from a male and female die, but rather than having only embossed and de-bossed surfaces in it, it has graduated levels, creating a watermark with many shades of light penetration. This is called a shadowmark, a light-and-shade watermark, or a chiaroscuro watermark.

Watermarks were used in paper by the end of the thirteenth century. They can appear anywhere in a sheet that the papermaker desires, but the standard placements are either in the center of the sheet or, more common, in the center of one-half of the sheet. As I have noted, many sheets have two such marks, the main one called the watermark, the other called the countermark. Since they yield a thinness to the paper and might affect the printing of the sheet, printers folded the sheets in such a way that the watermarks usually fell into margins. As noted, they can reveal the name or logo of the paper manufacturer, images of animals, buildings, hands or other body parts, geometrical designs, dates, or anything else desired. Paper made specifically for an artist can be fashioned with the artist’s name in the watermark.

There is a vast literature on watermarks, for a study of them can help with the dating and localization of otherwise anonymous documents and books. One should probably start with the monumental volumes compiled by Charles M. Briquet, *Les Filigranes: Dictionnaire Historique des Marques du Papier des Leur Apparition Vers 1282 Jisqu’en 1600* (Geneva: 1907, or one of the later reprints). The Paper Publications Society of Hilversum, Holland, has published many grand volumes that are compendia of watermarks.

PAPER SIZES

Paper made by hand was produced in many sizes, there not being any standard sizes that printers demanded. The size of any handmade sheet is determined by the inner dimensions of the deckle. Throughout Europe, sheets were made from fairly large to quite small, and each size was given a name—though, of course, the dimensions represented by any given name are approximate. The following chart

reveals approximate sizes since the dimensions varied from paper mill to paper mill and from country to country. The table uses English terms; the nomenclature in other countries obviously differs. (This listing of Paper Sizes was adapted from Labarre.)^[19]

E.J. Labarre, in his extraordinary *Dictionary and Encyclopaedia of Paper and Paper-Making*, lists over 200 paper sizes, each with its own name and particular dimensions. The most common of them are listed here, the dimensions given being approximate since papermakers throughout history used whatever size molds they had available for them, and there was no standard for any given book format, broadside, or other use. Other sources will give the same or similar names, but sometimes with varying dimensions (Table 1).

PAPER WEIGHT

Paper is often spoken of in terms of its weight. We use “20 lb. bond” for professional correspondence, “16 lb. paper” for taking notes, “24 lb. paper” for charts, and so forth. The terminology emanates from the weight of a ream of the full-size sheet. So a ream (in the United States this is 500 sheets; in England it was 480, but now the British use 500 as well) of full sheets of paper that weighs 20 pounds yields “20 lb. paper.”

The Wikipedia says it this way:

The basis weight of paper is the density of paper expressed in terms of the mass of a ream of given dimensions and a sheet count. In the U.S. system, the weight is specified in avoirdupois pounds, and the sheet count of a paper ream is usually 500 sheets.^[20]

Papers created for different purposes have different base (or basis) weights since the “standard size” of a sheet differs depending on its use (see Table 2).

The base weight of a sheet of Index bristol is higher than is the weight of Tissue, though two sheets are exactly the same size.

GRAIN OF PAPER

When a sheet of paper is hand made, the vatman shakes the fibers over the surface of the mold, forwards, back, and side to side, in such a way that the fibers get distributed in no particular order of alignment. On a Fourdrinier, however, since the screen on which the paper is formed moves constantly in one direction, the fibers tend to line up in that direction, creating a grain in the sheet. The grain can be seen under a microscope, or one can tear the sheet. If a newspaper is torn in one direction, the tear goes straight—with the grain. If it is torn in the other direction, the tear will be jagged and crooked—against the grain.

Table 1 Names of paper sizes.

Names of paper sizes	Sizes	Paper weight
Emperor	72 × 48	W, D
Quad	56 × 38	P
Double Atlas	55 × 31½	P
Antiquarian	53 × 31	D, B
Quad Royal	50 × 40	P
Quad Demy	45 × 35	P
Double Demy Oblong	42 × 16	W
Double Elephant	40 × 27	W, P, D, B
Double Royal	40 × 25	P, W, D, B
Double Demy	35 × 22½	W, P, D
Colombier	34½ × 23½	W, D, B
Atlas	34 × 26	W, D, B
Double Folio	34 × 22	W
Double Large Post	33 × 21	W, P, D
Double Post	30½ × 19	W, P, D
Imperial	29 × 22½	Wp
Elephant	28 × 23	W, P, D, Wp
Double Foolscap (also called Chancery)	26½ × 16½	W, P, D, B, Wp
Super Royal	27 × 19	W
Cartridge	26 × 21	Wp
Royal	24 × 19	W, P, D, B, Wp
Sheet and a Half Post	23½ × 19½	P
Demy	22½ × 17½	P
Medium	22 × 17½	W, D
Large Post (also called Draft, Medium, or Double Small Loaf)	21 × 16½	W, P, D, B, Wp
Small Demy (also called Demy)	20 × 15½	W, D
Copy (also called Tea Copy)	20 × 16	W, P, D, Wp
Post	19 × 15½	W, P
Crown (also called Single Small Hand)	20 × 15	W, P, D, B, Wp
Small (also called Pinched Post)	Post 18½ × 14½	W, P, D
Foolscap	17 × 13¼	P
Foolscap (also called Brief, Small Foolscap)	16½ × 13¼	W, D
Pott	15 × 12½	W, P, D
Half Crown	15 × 9½	D
Half Foolscap	14 × 9	D

Dimensions are given in inches, and a letter following each size indicates the use for which the paper was originally intended: W, Writing; P, Printing; D, Drawing; C, Cards; B, Boards; Wp, Wrapping. Smaller sizes of sheets for cards, notes, and envelopes are not listed here.

Printers and bookbinders must be particularly careful in their work, getting the grain to align throughout the work (usually vertically). It should be added, however, that handmade and machine-made sheets, composed of the same fibers and no other additive, will be of just about equal quality. Because a piece of paper is machine made does not mean that it is of inferior quality to a handmade one. The only difference between them may be the grain.

Table 2 Paper sizes.

Paper type	Paper size	Number of sheets
Bond, writing, ledger	17 × 22	500 sheets
Manuscript cover	18 × 31	500 sheets
Blotting	19 × 24	500 sheets
Box cover	20 × 24	500 sheets
Cover	20 × 26	500 or 1000 sheets
Bristol and tag	22½ × 28½	500 sheets
Tissue	24 × 36	480 sheets
Newsprint	24 × 36	500 sheets
Hanging, waxing, bag, etc.	24 × 36	500 sheets
Book, text, offset	25 × 38	500 sheets
Index bristol	25½ × 30½	500 sheets
Paperboard (all types)	12 × 12	1000 sheets (1000 square feet per ream)

PAPER PRESERVATION

Simple waterleaf (that is, unsized paper), if it is made from clean water and basic alkaline fibers, is alkaline (with a pH over 7), and will not deteriorate unless it is exposed to acids, high humidity and water (which will produce mildew), fire, or other deleterious agents. Hence, paper produced in the fourteenth century should be good as new if it has been stored properly.

As noted above (under “Paper fibers”), chemical pulp, and even good papers made from nonacidic materials, exposed to bad conditions (especially high humidity), will tend to show signs of deterioration. Papers that have been in a moist atmosphere may show “foxing,” the little orange or black spots that form from spores that are activated by water.

The best environment in which to store paper for its longest preservation is in a deep freeze. But that renders the materials inaccessible and creates other problems when the materials need to be used. For most libraries and other repositories, a steady environment of 68 degrees (±2°) and 50% humidity (±2% points) is ideal.

Further, steady readings of temperature and humidity are better for paper than are fluctuations since paper will expand and contract with such changes. It is better to have paper-based materials in a temperature, say, 75 degrees at all times than it is to have the temperature fluctuating frequently between 65 and 75.

Papers should be kept away from lights, especially fluorescent lights with their ultraviolet rays, which are damaging. Sunlight also has UV rays, so paper should be kept in acid-free folders or in books away from direct light. Even incandescent bulbs can be damaging over time.

Air filtration is a must, since outside air, especially in cities, can have acids that will harm paper. Witness the tombstones in New England graveyards, with their carving completely worn away.

Papers with acid in them can be deacidified, but the process, which leaves an alkaline base (like calcium carbonate) in the sheets, will not strengthen the papers nor whiten them.

Good storage conditions and careful handling will lengthen the life of all paper items.

Finally, paper is a fine material for preservation. In the Florence flood of November 1966, millions of books were damaged. The bindings of most of those bound in leather and vellum were beyond repair. Those in paper survived to a much greater extent. The paper could be washed the way the leathers could not.

PAPER DECORATION

Over the centuries, paper has been decorated in a variety of ways, for many reasons. There are many enhancing techniques, but the most common are marbling and paste paper decoration.

While marbling is probably a sixteenth-century Persian invention, the true history is shrouded in mist. The Japanese had their own version of “marbling,” called “Suminagashi,” in which the artist, holding one or more brushes containing the pigments, would put droplets of colored pigments onto the surface of a water trough by touching the tips of the ink-laden brushes to the water. The drops would spread out, often with a series of drops placed inside previously laid-on drops. With a fan, a hand, or breath, the artist would make the rings move into various loosely controlled “patterns.” When the desired distribution of lines was achieved, the artist would place a sheet of Washi (handmade Japanese paper) onto the surface and the pattern would transfer to the surface of the sheet. If the paper was waterleaf, as were many of the soft Japanese papers, the design would impregnate itself into the sheet and be visible from both sides.

There is no way to know if this decorative paper was known to the West, or if it had any direct or indirect effect on the development of marbling in the Middle East or the West.

Marbling is quite a simple process to do, but preparing all the equipment and supplies for it is not. One needs a tray to marble in, water, a thickener for the water, brushes and combs and other tools to create the patterns, pigments, paper, ox gall, and alum.

Sheets of paper are prepared by having a wash of alum brushed over them as a mordant—that is, the binder that will allow the pigments to stick to the sheet. The sheets are then allowed to dry.

The size is prepared: water slightly thickened with Irish moss, carrageen, or gum tragacanth. When it is poured into the trough, it looks like water, but it is thick enough that drops of pigment will “sit still” on its surface.

The pigments can be any kind: watercolor, gouache, acrylics, or other kinds. A color is put into a container

(like a cup) and is mixed with ox gall, the thick, brown, odorous liquid from the gall bladder of an ox. The ox gall allows the pigments to float on the top of the size, to spread out into circles (the more ox gall in the pigment, the more the drops spread), and to touch other drops without blending.

Pigments are placed carefully or dropped stochastically onto the surface of the size. They are then manipulated with combs or needles or other tools into a pattern, still sitting on the size in the trough. A piece of alum-coated paper is placed carefully over the surface and the pattern transfers to the sheet. This lifts most of the pigment off the size, so the process must be done from scratch for each sheet. Hence, no two sheets of marbled paper are alike.

The method produces patterned sheets, many of the patterns with names, many with representational art on them, like flowers, animals, calligraphic words, and so forth. Some of the decorative patterns have become familiar over the centuries: bouquet, French snail, Dutch curl, zigzag, chevron, non pareil, Spanish wave, and so on. The process can also be done with no combs, but with the pigment droplets falling at random onto the size. This produces sheets with no particular pattern, but recognizable nevertheless, and often named (like “vein,” “stone,” “Stormont,” and the like).

While the method of marbling was kept a secret during the earlier centuries of its practice, in the nineteenth century the “secrets” were exposed, and today there is a worldwide interest in the art, with practitioners all over the world.

About contemporaneously to marbling, Paste Paper emerged as a way of enhancing books and other surfaces. Both methods (paste and marbling) were early on used by (and even practiced by) bookbinders, who saw them as a way to enhance the beauty of a book at a fraction of the cost of using leather.

Paste paper decoration is much simpler than marbling and is easier to master. One mixes up a batch of paste (wheat starch or rice starch works fine), mixes in a pigment, and spreads the colored paste with a brush or sponge over a sheet of dampened paper. While the pigment is still wet, any way it is touched will disrupt the smooth lines of the brushed-on paste. Touch the paste with a fingertip and the result is a little circle in the paste.

At this point, the artist’s imagination comes into play. Using any of a myriad of tools, the artist manipulates the paste into an endless selection of patterns. When the pattern is as the artist wants it, she or he stops moving the paste around and sets the sheet out to dry. The results can be astonishingly beautiful sheets.

There are many other ways to decorate paper: block printing, batik, tie-dye, folding and dyeing, impregnating or covering the sheets with materials like sparkles, pigments, or threads, weaving strips of paper together, stenciling, pricking, and so on.

The use of decorated papers in books has been around for two millennia. The attractive materials enhance the volumes and protect them. The papers are less expensive than leathers or parchments, and they do not deteriorate the way poorly processed leathers will.

Modern Papermaking

Today, the basic methods of papermaking that were invented in China more than 2000 years ago still hold: identification and gathering of fibers, preparation of fibers (breaking the raw materials down into tiny fibers); distributing the fibers over a screen to form the paper; removing the paper from the screen and drying it.

Even before the coming of the Industrial Revolution, papermaking was mechanized with the inventions of wove screens, the steam engine, and the Fourdrinier. The need for increasing amounts of paper in the nineteenth century led to experimentation with nontraditional fibers (hemp and cotton—essentially old rags—and various grasses). Wood pulp was the “final” choice since it is abundant, relatively renewable, manipulable, and inexpensive.

Just about all commercially made paper today comes from Fourdriniers, giant machines that perform many functions beyond the initial formation of the paper. Modern papermaking begins in the forest, with the harvesting of the trees, which are taken to the mill and debarked and chipped (the bark is removed and the wood is broken down into chips). It is then macerated, usually after being subjected to an acid bath which begins the breaking-down process. The pulp is then washed, refined, cleaned, and usually bleached. At this stage, if the washing does not remove all of the acids used to break down the pulp, or if the bleaching leaves an acid deposit in the pulp, inherent vice may wind up in the final paper.

At this point, the paper is transferred to the part of the Fourdrinier that actually forms the paper. Many kinds of additives can be put into the giant vats, like colors, inclusions to add tiny flecks to the papers, deacidifying agents like calcium carbonate, coating materials, sizing, and so on.

The pulp is then pumped over the moving screen, and the actual paper formation takes place. Just as the fibers are beginning to settle onto the screen, a dandy roll, a large cylinder containing a raised pattern, rolls over the screen, displacing the fibers to thin out the papers to create watermarks. Water drips through the screen and the paper is now formed into sheets that are as long as the manufacturer wants them to be. That is, if the machine keeps running and the screen keeps moving, and if the pulp continues to be distributed over the screen, an “endless web” of fibers will continue to form paper.

The paper now leaves the “wet end” of the Fourdrinier and enters the “press section,” then it goes on to the “dryer section,” and finally it goes to the “calender section.”

The machine performs many functions, so on the Fourdrinier are other rolls and other features: vacuum pumps to remove water, warm cylinders to dry the paper, calendering cylinders to burnish (smooth out) the paper, and so forth.

Paper is also produced from recycled materials, but each time old papers are prepared for new manufacture, the fibers are macerated further than they were the first time, they get smaller, and the resulting paper is generally not as strong as was the paper created from “new” materials. Often recycled pulp is added to new pulp to reduce costs and to keep the papers fairly strong. Though part of the manufacture of recycled paper is de-inking, the process still yields paper that costs less than does paper manufactured from new materials. More than half of the paper produced in the United States today contains recycled fibers.

If one considers the vast number of uses of paper today and the thousands of manufacturers of so many kinds of paper worldwide, it is easy to see why statistics on the quantities of paper manufacture are difficult to compile.

University of Illinois Library School Professor F.W. Lancaster, in the 1970s, predicted a “paperless society.” He did not mean this literally, but he did predict that, early in the computer age, society would be in a position to reduce its reliance on paper if it wanted to, thanks to the memories of computers. Taken out of context innumerable times, this phrase has proven correct and incorrect. It is true that a vastly increasing amount of information is being stored in digital form, thus reducing the need for paper. But the computer has given the world the capacity to print out (download) draft after draft of documents, millions of bits of information from the World Wide Web, photographs and other illustrative matter, and an endless stream of other materials, thus immeasurably increasing the amount of paper used today.

Hence, the amount of paper produced today continues to accelerate, and there is no end in sight.

Modern Hand Papermaking

While the great preponderance of paper today is machine made, there has been, for more than 60 years, a desire to return to the hand crafts.

Douglas Morse Howell was one of the earliest proponents of “modern hand papermaking,” having set up his own paper mill in 1946, making paper for artists such as Jackson Pollock and Lee Krasner. Many others followed his lead, and today there is a small but thriving hand papermaking community in the United States. There is even a fine magazine/journal, *Hand Papermaking*, that in 2008 hit its 25th year of publication and is still going strong.

There is still a call for handmade papers throughout the art and book world, for printers, artists, and those who love the feel and rattle of a handmade product.

Several operations have been around for decades, like Henry Morris’ private press, The Bird & Bull Press, which has specialized in publishing books about books, with a sub-specialty on handmade paper. Morris’ own work *Omnibus* (Bird & Bull Press: North Hills, Pennsylvania, 1967) is a classic in the field, along with Walter Hamady’s *Hand Papermaking* (Perishable Press: Mt. Horeb, Wisconsin, 1982).

Many artists, like Robbin Ami Silverberg in Brooklyn, produce their own handmade papers for the books they print. And in fact, an extensive network of fine presses in the United States (and throughout the world) use only handmade papers in their work.

While Wookey Hole Mill in Somerset, England, and its compatriot mill in Maidstone run by Barcham Green and then by Simon Green, have closed, other mills are still holding on. For nearly 40 years, Kathryn and Howard Clark have run Twinrock Paper Mill in Indiana. Tim Barrett, with extensive training in Japanese papermaking, teaches the subject at the University of Iowa. And papermaking classes are offered throughout the country, as a glance at any of the *Hand Papermaking* newsletters attests.

Running alongside the papermakers are those decorating the papers: marblers, paste paper makers, book artists needing specific decorative sheets for their publications, and many others. In the United States alone there are hundreds of marblers and scores of people working in paste papers.

In Europe the situation is comparable, with active mills in Germany, France, Czechoslovakia, Italy, and Spain, to name just a few countries. While some mills are there for demonstration only, others, with many private practitioners, are at work producing papers for printers and artists. And in the Far East, the Chinese, Japanese, Thais, Nepalese, Indians, Koreans, and many others are making splendid papers. Even in Africa there is a rudimentary handmade-paper industry. The continued demand for the product from artists, kite makers, scrapbook enthusiasts, origami experts, bookbinders, printers, and even people looking for lovely wrapping papers or greeting cards has spurred interest in the craft, and the production of handmade paper in the world today seems endless.

OTHER MATTERS

Today there are several associations of papermakers, including the International Association of Paper Historians (see <http://www.paperhistory.org/>); the International Association of Hand Papermakers and Paper Artists (<http://www.iapma.info/>); many professional and commercial paper associations; and smaller groups throughout the world whose interest is commercial, noncommercial, handmade, decorative, or other kinds of paper. (For instance, there are the American Forest and Paper Association, the National Paper Trade Association, Pulp & Paper

Product Council, Canada, and dozens of others in North America alone.) Worth repeating is the fact that in the United States an important magazine has been published for over 25 years, *Hand Papermaking*, keeping its readers up to date on all kinds of hand papermaking throughout the world.

The medium is important enough to have several museums devoted to it. For instance, The Robert C. Williams Paper Museum at the Institute of Paper Science and Technology in Atlanta, Georgia, contains, among many other things, the original Dard Hunter Collection of Paper. In Europe there are more than three dozen paper museums,^[21] and in Asia there are several, including the Pan Asian Paper Museum in Korea, The Paper Museum in Tokyo, and the Ino-Cho Paper Museum in Kochi Prefecture.

The importance of paper in our lives cannot be understated. It is perhaps the most vital material in the world for the advancement of learning, the recording of history, and for thousands of other common uses. It is also one of the most versatile materials, manifesting itself in endless appearances, decorations, shapes, thicknesses, and colors. In the library world, there would be no library world without it.

History of Public Libraries *[ELIS Classic]*

Frank B. Sessa

University of Pittsburgh, Pittsburgh, Pennsylvania, U.S.A.

Abstract

The history of public libraries is surveyed, with particular emphasis on public libraries in the United States.

—*ELIS Classic*, from 1978

INTRODUCTION

It was suggested that the contemporary public library in the United States can be “understood to some degree through the historical perspectives of its origins in the 19th century. . . .” The library described in that context is a public institution supported by taxation, one that opens its collections, facilities, and services, without distinction, to all citizens. With minor variations because of differences in political philosophy, national experience, and state of educational development, this statement may be applied equally to the public libraries of Asian countries, of Eastern and Western Europe, of Australia and New Zealand, and of other parts of the world today in which public libraries have been established. The fact remains, however, that the “public library as we understand it is an Anglo-Saxon idea.” It developed in England and America at about the same time, “and was original in both countries.”^[1]

HISTORY OF THE PUBLIC LIBRARY

A century ago, William Frederick Poole, then librarian of the Chicago Public Library, wrote:

The public library is established by state laws, is supported by local taxation and voluntary gifts, is managed as a public trust, and every citizen of the city and town which maintains it has an equal share in its privileges of reference and circulation.^[2]

At that point, three-quarters of the way through the nineteenth century, Poole was writing of a well-established social and educational agency. Its roots, however, lay at least two millennia in the past. The term “public library” may be applied to some libraries in the pre-Christian era, but its meaning differed considerably from that of today; the libraries were public in a far different sense than present public libraries. It might be said that they were public as opposed to the libraries that were the private possessions of individuals who restricted use to their own purposes. Ancient “public” libraries were, of

course, for the use of the founder but also for scholars, students, priests, and officials who were permitted to use their collections for approved study.

It was suggested by the writer Aulus Gellius that near the middle of the sixth century B.C. the tyrant Pisistratus “collected a large library of books and later gave it to the city of Athens, where it was opened to the public.” There is no corroboration of the account, however.^[3]

Julius Caesar had the idea of founding a national or public library in Rome “to open to the public the greatest possible libraries of Greek and Latin books.” He planned to place Marcus Terentius Varro in charge, an erudite and prolific writer.^[3,4] Caesar was assassinated before he could carry out such a project. It fell then to C. Asinius Pollio to provide the first public library in Rome in the Atrium Libertatis, 39 B.C.^[3]

Rome, by the end of the fourth century, was reputed to have 28–30 public libraries. Again, these were not the public libraries of today but were available to those who could and would use them. Rome had, after all, in the imperial period, an increasing number of persons who were literate. There were booksellers in Rome and in many of the larger cities of the provinces. It was fashionable, too, to have books in one’s home. As the Roman Empire declined in the West, the libraries also declined, as did book publishing and acquisition.^[5]

A step closer to the modern public library was the “town library” that came into existence in the fifteenth to nineteenth centuries in England, Scotland, France, and Germany.

The early libraries in England were founded as gifts of individuals or by a “public and joint-stock contribution, and then entrusted to the guardianship of the respective municipalities.” Norwich, Leicester, and Bristol in England had examples of such town libraries founded in the first third of the seventeenth century, but their books and quarters after some vicissitudes ended up in a state of neglect or in the possession of a private society. In Bristol, as an example, the library, the structure provided to house it (Library House), and the books came into the possession of a private subscription library that relieved the Town Council of the need of its support. At Leicester, the town

library, founded in 1632, was in the latter part of the seventeenth century permitted to sink “into careless guardianship and ultimate neglect.”^[6] Scotland had to wait until late in the eighteenth century (1791) for a library, which soon was forced to become a subscription library to continue in existence.^[7]

There was at least one other English public library that deserves mention, the Chetham Library in Manchester, founded in 1653, and the gift of Humphrey Chetham, wool-factor and money-lender, who left £1000 to be used for books “for or towards a Library within the town of Manchester and an additional £1000 for the purchase of ‘some fit place for the said library.’” There were £200 additional for the purchase of “godly English books, such as Calvin’s, Preston’s, and Perkin’s works.” After other bequests—including a Hospital for Maintenance and Education of poor boys—had been met, the residue of the estate was to go for the further purchase of books. The income ran between £750 and £500 annually. By 1826, the library was reputed to have 14,276 items, the larger portion of which were folios and quartos. The next several decades did not do much for the library.^[6,8]

Many of the town libraries in France suffered the same fate—“a gross breach of trust”—as those in England, and disappeared. In many other cases, however, the library was quite successful and continued in existence.^[7] The library at Caen, for example, was established in 1431, and after suffering from the effects of religious wars and suppression, it was restored in 1736. Subsequently, it received books at the time of the suppression of the Jesuits and further contributions of books were made after the Revolution. In 1809, “when it was organized for public use,” it had some 25,000 volumes and continued to grow.^[7] Edwards also mentioned a library at Lyons, established in 1530, that early in the nineteenth century had 120,000 volumes and 1500 manuscripts.^[7] Edwards was particularly impressed with the state of libraries in the provinces of France at the time he was writing (1850s), the result of the fact “that in some eminent instances French Municipal Councils have consistently displayed, during a series of years, an enlightened appreciation of the value of store-houses of learning.”^[7]

In Germany, town libraries were established in Ratisbon (1430), Ulm (ca. 1440), Erfurt (1440), Nuremburg (1445), Hamburg (1529), and Lübeck (1530), to cite a few. In general, they grew out of bequests. In the early days, their contents were largely juridical, but when the religious houses were dissolved, many came into a number of rare manuscripts. As in France, a number continued in existence and had important collections by the mid-nineteenth century.^[7]

THE UNITED KINGDOM

In the United Kingdom, there were a number of other forerunners of the public library. There were the parish

libraries of the Reverend Thomas Bray that provided collections for laymen as well as for clerics. In Scotland, the Reverend James Kirkwood developed an elaborate scheme for “founding and maintaining bibliotheks in every paroch throughout this kingdom.” The scheme entailed providing a place for books in each parish, handing over to the library the personal books of the minister, cataloging of books, and making of four copies of each catalog, one of which would go to the principal library in Edinburgh that would make a general catalog of all books in kingdom. The scheme called for compensation to the minister for his books, cooperation between parishes, the lending of books, book binding, and ultimately, a “Printing-House and Paper Manufactory.”^[9] The Reverend Samuel Brown of East Lothian developed a plan involving “itinerating libraries,” through which there would be provided “a library or division of 50 books in each town or village of a county.” The library would remain in the town 2 years, move to another town, then move again in another 2 years, and so on. In each case, the collection would be replaced by another. The plan went into operation in 1817 in Haddington, where Reverend Brown was then provost, and in four other villages. In general, the circulation was good in the first year and fell off fairly sharply in the second year. The books had a strongly religious cast, but there were books of a “plain and popular nature” in the arts and sciences as well as in history, biography, and travel. The plan developed to the point that by 1836 there were some 47 libraries with 2380 volumes. After the death of Reverend Brown in 1839, the project slowly declined, partly because there was no one to offer the management and financial support he had supplied.^[9]

Also a forerunner of the public library was the social library: both proprietary and subscription. In larger cities, circulating libraries (strictly profit-making ventures) appeared, particularly in Scotland in the early eighteenth century.^[9] For the workers, there were apprentices’ libraries and mechanics’ institutes. These will be discussed in some detail later.

Toward the middle of the nineteenth century, the modern public library moved closer to reality by the passage of the Museums Act of 1845, primarily the work of William Ewart, who had been a member of Parliament for Liverpool (1830–1837) and was then member for Dumfries. Impetus for passage of the act had come from a meeting held in Manchester in November 1844, a meeting presided over by Richard Cobden. Joseph Brotherton, member for Salford (also in attendance), was influenced to appeal to William Ewart to work on the proposal. The result was passage of an act “Encouraging the Establishment of Museums in Large Towns.” It authorized the levying of a ½ d. rate in towns of not less than 10,000 population for the erection of museums of science and art; the act provided only for the building. An admission charge of 1 d. was authorized for support. Within a short time, three

towns—Canterbury, Warrington, and Salford—had taken advantage of the act to set up combined museums and libraries. The library at Canterbury, established in 1847, grew out of the purchase of the museum and library of the Philosophical and Library Institution. Warrington followed in the next year with the location together in rented quarters of the museum of the Warrington Natural History Society and the collections of the Warrington Subscription Library. There was a full-time curator who also served as librarian. Salford established a museum and library in 1849, although it was not opened until the following year.^[10]

William Ewart was further stimulated to work toward a public library act by an article written by Edward Edwards, “Statistical View of the Principal Libraries in Europe and the United States.” Edwards, a prolific writer on the subject of libraries, was then a supernumerary assistant at the British Museum and had testified before an earlier Select Committee inquiry into British Museum activities. Ewart drew upon Edward’s knowledge of libraries and by 1849 had convinced Parliament to establish a Select Committee to inquire into the establishment of “libraries freely open to the Public, especially in large towns.” The committee and its successor recommended, after inquiring into libraries on the Continent and in the United States, that Parliament authorize town councils to levy a small rate to establish and support public libraries.^[6,9,10] In February 1850, Ewart moved for permission to introduce “a Bill for enabling Town Councils to establish Public Libraries and Museums.” After considerable debate, the motion passed. After further debate and some amendments, the bill went to the House of Lords and then “received Royal assent” on August 14.^[6] The main provisions of the act were that corporate towns of 10,000 persons might levy a ½ d. rate to buy land and build buildings for libraries. The act of 1850 applied to England and Wales. It was extended in 1853 to the “Municipal Boroughs in Ireland and the Royal and Parliamentary Burghs in Scotland.”^[9]

The Museums Act passed with rather general support, but the Public Library Act ran into considerable opposition. Whatever popular support for it there might have been, it was not marshaled, partly because the franchise was not then as widely extended as later. It can be said that it was sponsored by a strong, determined minority drawn from members of the library profession and from the upper strata of society. In general, the arguments ran to extending the benefits of reading to the lower classes. The benefits were seen as social, moral, and educational. Brotherton argued that reading would reduce crime and “provide the cheapest police that could be gathered.” Others argued that it would keep workers from the evils of the gin shops. Opposition came from those who objected to an increase in rates and those who feared that agitation and social unrest would result.^[10,11]

Libraries were rather slow to appear. Edward Edwards suggested that Manchester was the first to establish a library

under the act, for the “preliminary subscription towards the expenses of its foundation had been set on foot, whilst the Bill was still pending in the House of Commons, by Sir John Potter. . . .” The poll at Manchester was not taken until August 1852, “when a library of 21,000 volumes was in complete working order.” The subscription raised amounted to £12,823.^[6] The first city in which a poll was taken was Norwich, however. Although the poll was taken on September 17, 1850, no service was begun until 1857.^[8,10] Twenty-three libraries were opened between the years 1851 and 1862, and 98 more between 1868 and 1886, for a total of (with the four previously established) 125.^[8,10]

Ewart attempted to have the act of 1850 amended in 1854, but it was not until the next year that the amended act became law: *An Act for further promoting the establishment of Free Public Libraries and Museums in Municipal Towns, and for extending it to Towns governed under Local Improvement Acts, and to Parishes*. It reduced the number of inhabitants necessary to qualify under the act from 10,000 to over 5000. Two neighboring parishes with populations that together aggregated more than 5000 persons and with vestries that chose to unite to establish a public library might do so. The rate was set at “one Penny in the Pound on the rateable value of the property assessed,” and “Books, Newspapers, Maps, and Specimens of Art and Science, Fuel, Lighting and other similar matters” might be purchased.^[6]

Over the years, there were a number of Public Libraries Acts, but the changes were minor, “no more than further provisions for adoption, area definitions and powers for Authorities to take joint action.”^[8] In 1892 (June 27), a new Public Libraries Bill received royal assent. The act repealed former legislation and, in effect, consolidated previous advances and changes. The act of 1919 not only permitted the development of urban library service by removing the rate limitation, but it also gave library powers to counties. A major drawback of the national library legislation of the latter half of the nineteenth century had been the continuation of the penny rate limitation. A number of library authorities, about 30 by 1900, had freed themselves of the limitation “by means of clauses in Local Acts.”^[8] It was not until the close of the year 1919 (December 23), however, that the rate limitation was removed. Other provisions of the act were important too. County Councils might now adopt the Public Libraries Acts for all or part of their areas. They might accept library powers from existing library authorities or give up, with approval of the Education Committee, their powers “in respect of any part of its library area to permit the establishment of an independent library service.”^[8,10] As Lionel McColvin pointed out, the county system was in position to serve “people living under a variety of circumstances—in isolated farms, in little villages, in mining and industrial townships or market towns, in new towns and in the suburbs.”^[12] This act was a dominant factor in library development from 1919 to 1965.

Andrew Carnegie contributed significantly to the public library movement in the United Kingdom, as he did in the United States. His first gift was that of £8000 to his native Dunfermline in 1879. By 1883, the library had opened.^[8]

Carnegie made subsequent grants in Scotland and in England. As in America, grants were usually for buildings and equipment, not for books or operation. By the time of his death, about half the library authorities in England and Wales and more than half in Scotland had profited from his generosity. In 1913, he created the Carnegie United Kingdom Trust (CUKT) with a capital of £2,000,000, and he indicated libraries were a high priority. Most of the public library development had come in the larger cities and towns. It was logical, therefore, that the Carnegie Trust would turn its attention toward helping the rural areas of the counties. Various local “schemes” for assisting public libraries were used as experiments, such as the Workshop Authority project to supply book service for the nearby rural parishes of Nottinghamshire.^[8] At Staffordshire, the Trustees of CUKT funded a “central Repository of books...from which should be dispatched to the Schools of the County consignments of books which would reach their readers through the agency of the schoolmasters and the schoolchildren.” The plan had first been suggested to Oxford, which turned down the offer of funding in the amount of £5000. When the new Public Library Act of 1919 provided for the establishment of County Library Authorities, the trustees of the foundation began to make grants to the authorities in terms of books, book boxes, shelving, and other equipment.^[8] One measure taken by the trustees to further the cause of county libraries was a grant of £4000 for the provision of a County Library sign that became a familiar reminder of library service across the countryside and of Carnegie “benefaction to a grand total of £500,000.” For the early years following the passage of the 1919 act, service consisted of boxes of books that eventually gave way to the “library van” or bookmobile. Gradually, in the smaller urban areas subject to the County Library Authority, a room or library building was provided. Utilizing a provision of the 1919 act that permitted the levy of a rate above the normal county rate to provide branch library service, counties began to provide service on the urban pattern.^[8]

Library service remained uneven, however, for the populations served by local authorities varied from 30,000 to 1,000,000 or more persons. The smaller authorities had neither the manpower nor the financial resources to provide a satisfactory level of library service.

The number of public library authorities in England and Wales was sharply reduced (345 to 83) by comprehensive local government legislation, the Local Government Act of 1972. The amalgamation was to be accomplished by April 1, 1974. Most of the new authorities had populations of 200,000 or more persons, which made it possible to have greater financial resources than before. The London area, reorganized in 1965, was not changed.

THE UNITED STATES

In America, the first library to meet the test of a modern public library was that established in Peterborough, New Hampshire, in 1833. Money originally appropriated by the state for other purposes (a state university) was put into a Literary Fund and made available to towns to devote to the support and maintenance of “common free schools, or to other purposes of education.”^[13] The purpose to which Peterborough put the money was to provide books for a town library to which there would be access without charge. The collection, reports Jesse Shera, was rather like those of the social libraries of the day.^[13] The library’s true significance, however, was that

for the first time an institution was founded by a town with the deliberate purpose of creating a free library that would be open without restriction to all classes of the community—a library supported from the beginning by public funds.^[13]

Before the establishment of the Peterborough library, there had been books and libraries in America for some two centuries, for a number of private libraries had come with the early settlers. Several—like those of Elder William Brewster of Plymouth Colony and John Winthrop, Jr., governor of Connecticut—were, in the early part of the seventeenth century, quite impressive. In New England at the close of the century, the largest private libraries were those of Increase and Cotton Mather; in Westover, Virginia, Colonel William Byrd is reputed to have had a library of 4000 volumes, and in Philadelphia, James Logan, a library of 3000 volumes.^[3,14] The number of those who read was, as in the mother country, rather limited, although there were presses in the colonies and booksellers as well.

Robert Keayne—a merchant described variously as “a conscientious & upright man in the generall,” an “extortioner,” “contentious and stubborn,” and fined for “profiteering”—bequeathed a public library to Boston in the 1650s. In his will, written between August and December 1653, he provided that £300 were to be set aside for public use, in particular, a Town House in which a room was to be provided for a public library. Included in the bequest were his “three great writing bookes which are intended as an Exposition or Interpretation of the whole Bible.” His son and his wife were to choose from his personal books those they wished, the balance to go to the library. In the event the town of Boston failed to act upon his gift by providing the Town House, the money and books would go to Harvard College. The building was erected and put into use, but it suffered two fires. One in 1711 destroyed the building, but the library was largely saved. The restored structure and the library were totally consumed by fire in 1747. No more was heard of the library. Keayne had hoped his example would lead others

to donate books, but few books came by way of contribution. The library served for almost a century as a repository of town records and was generally known as a public library owned by the town and supported by it.^[13,15] Another early library for the public resulted from the will of Theophilus Eaton, governor of New Haven, which provided that the books formerly belonging to his late brother Samuel be held in trust for a college that was to be established in New Haven by John Davenport. Davenport left the colony, and the college failed to materialize. The books then belonged to the town and are believed to have eventually found their way into the schoolhouse, where they were kept but seldom used until sold in 1689 for “forty pounds of rye and thirty-two bushels of Indian corn, appraised at 12 pounds, 18 shillings.”^[13,15] Concord, Massachusetts also had a library owned and supported by the town before 1672. There were other towns in New England that owned and supported libraries in the early years of the eighteenth century. Shera mentions three in Massachusetts: Oxford (1719), Lancaster (1731), and East Sudbury (1726). The first collection was a gift, but the latter two were purchased at town expense, kept in the meeting house, and made available to the townspeople.^[13]

At the beginning of the eighteenth century, there appeared for the colonists another source of books, the parish and provincial libraries instigated by the Reverend Thomas Bray. Dr. Bray was appointed commissary of the Anglican Church in the Colony of Maryland in 1695. He early realized that to supply ministers and missionaries for the relatively unappealing parishes in the colony, he was going to have to draw upon the “poorer and less influential men,” men who would have difficulty supporting themselves and could not be expected to provide themselves with a library, which Bray considered essential. A minister could do “his best only if he had ready access to a library. . . .”^[16] Bray was assisted in his work of getting libraries to America by two groups he was instrumental in forming: the Society for the Promotion of Christian Knowledge and the Society for the Propagation of the Gospel in Foreign Parts (SPG). Later in his life when he fell ill, he was assisted by a group known as Dr. Bray’s Associates.^[16]

Although his primary interest lay in Maryland, Bray made the effort to extend such libraries to all of the colonies. He thought of one large library in each colony, a provincial or general library, and of a parochial library for each parish. He also provided libraries for laymen. Bray served as commissary for Maryland from 1695 to 1704. In that period of less than a decade, he and those who worked with him established:

provincial libraries at Boston, New York, Philadelphia, Annapolis, Charleston and Bath, North Carolina. He provided thirty-nine parochial libraries, of which twenty-five were located in Maryland, although each of the other colonies had at least one such library. Finally he provided

over thirty-five layman’s libraries and sent over 35,000 religious books and tracts to the colonies for three distribution.^[16]

The libraries were not large; the largest, 1095 volumes, was in Annapolis and was considered the “Publick Library” of the colony. Governor Francis Nicholson, with a view to enlarging the collection, suggested that the king be asked for permission to divert some military defense funds for library. The Assembly, however, did not acquiesce.^[15] The library in Charleston had support from Bray, the Assembly, and the proprietors of the colony. In 1700, the Assembly of South Carolina passed a law, one of the earliest in America, that put the books in the “care” of the minister of Charleston, with a board of nine commissioners appointed by the Assembly to manage it. Use was without restriction. Books might be borrowed, the length of time depending upon the size of the books: “if a *Folio*, in four months time; if a *Quarto*, in two months time; if an *Octavo*, or under, in one month, upon Penalty of paying three times the full Value of the said Book or Books so borrowed, or damnifying the same.” The collections of the libraries were heavily theological but they were not entirely so. More than one-third of the initial purchase of books for the Charleston library were nonreligious. It was not Bray’s intention to supply a complete library for the parish. He hoped, although the hope was seldom realized, that there would be additions made locally to the collections.^[13,15,16]

In the main, the Bray libraries were not public libraries, even though a few were so designated. Quite a number of laymen had access to all of the libraries, for ministers permitted members of the parish to use some of their books. Their significance was that they “did much to enrich the book resources of the clergy in the American Colonies at the beginning of the eighteenth century.” Shera suggested further that their relationship to the public library movement was “more symptomatic than influential.” Laughter counters with the observation that “if the libraries had no effect, the SPG would not have continued sending such reading matter to the colonies, in an amount estimated to exceed 100,000 volumes.”^[13,16]

Of more significance in the chronicle of the predecessors of the public library in America was the social library, a library resulting from the association of a group of persons who contributed or subscribed money for the purchase of books. Title to the books remained with the association, although all contributors could use or borrow them. The library might be proprietary, that is, the members of the group subscribed to stock and owned shares; or it might be a subscription library for which the members of the group subscribed an initial fee, with which the first books were bought, and followed the initial subscription with the payment of an annual fee. Both the proprietary and the subscription libraries soon permitted nonsubscribers to use the collections upon payment of a

set fee. In general, these libraries were legal entities operating on a charter issued by the individual colonies and later by the states.^[13]

The movement toward the social library was started in America by Benjamin Franklin, who in late 1720s, was the organizer of a group interested in “socializing and debating,” the Junto. An experiment of pooling personal books to provide a resource for their debating material and for other use was not a success. Franklin then proposed a library provided by the subscription of 40 shillings by each member of the Junto and an annual fee of 10 shillings. Out of this proposal came the Library Company of Philadelphia, founded in 1731, often referred to as the mother of the social library in America. Before long, subscription libraries began to appear in all of the colonies.^[13]

Three other early major social libraries—like the Library Company of Philadelphia, still in existence—are the Redwood Library of Newport, Rhode Island, the New York Society Library of New York City, and the Charleston Library Society of Charleston, South Carolina.

The Redwood Library was founded in 1747 and was the first of these libraries in America to receive a charter. It too grew out of a discussion group, the Literary and Philosophical Society dating back to 1730, or at least the society seems to have been influential in Abraham Redwood’s offer to donate £500 if a company for the establishment of a library were formed. The offer was accepted, and money was pledged for a building on property donated by one of the society’s members. The Provincial Assembly issued a charter in 1747. By 1750, the library was in its own building, and 5 years later, Dr. Ezra Stiles (pastor at Newport, who later became president of Yale University) became its librarian. He seems to have devoted some of his time each week to the library, but the founder decried the Anglican influence of Stiles and those who controlled the library.^[15] According to Horace Scudder, the character of the original collection attracted Stiles to Newport. “The books bought with Mr. Redwood’s money were considered at the time the finest collection of works on theology, history, the arts and sciences in the American Colonies.”^[17] The library suffered during the Revolution, and in 1790, it was described as “in a sad plight and in the period of stagnation many books disappeared and about three quarters of the collection was lost.” The library achieved a “renewed prosperity” in the nineteenth century. In 1952, the library began a buying campaign to restore the original collection.^[18]

The New York Society Library, organized in 1754 as the City Library, held its first board meeting at the City Arms on Broadway. The meeting was concerned with the raising of money to erect and maintain a “publick Library.” It was reported that “not less than 70 gentlemen have already subscribed Five Pounds Principal and Ten Shillings per Annum, for that Purpose.” Soon, the 118 subscribers were asked to submit a list of books each considered to be desirable. To books purchased was added a collection of about 2000 volumes, known as the

corporation library. This was a gift to the city from two Anglican clergymen who were distressed with the paucity of reading material in New York: the Reverend John Sharpe, chaplain of Queen Anne’s forces in New York, who observed “there being no place I know of in America where it [learning] is less encouraged or regarded”; and the Reverend John Millington of Kensington, England, who found New York an “uncultured little city of seven thousand souls in the ‘Plantations in America.’” The latter left his books to the SPG to be shipped to New York. The library was open not only to city residents as subscribers but also to those who lived in the colony. Nonsubscribers might borrow books by leaving a deposit of more than one-third the value of the book or books taken. The library was first located in a room in City Hall with Benjamin Hildreth as library keeper, “who received £6 annually for ‘his Trouble and Care while in that Office.’”

By 1795, the library had erected its own building. It had fallen upon evil days during the Revolution but began to move toward recovery in 1788, when operations were resumed. A catalog of 1793 listed 5000 titles. In 1840, the library was located at Broadway and Leonard and remained there for 13 years. A large lecture room in these quarters permitted varied entertainment, discussions, and assemblies. Among those who appeared were Fanny Kemble, the Swiss Bell Ringers, Campbell’s Minstrels, and Edgar Allan Poe, who lectured on American poetry.^[17,19]

The Charleston Library Society was founded in 1748, the earliest proprietary library in America according to Edgar Reinke. Established by 17 young men, the number of members increased to 160 before mid-century. The library was granted a charter by the colony, confirmed by the crown in 1755. It began with the intent of acquiring magazine and pamphlet material but soon acquired books as well. The library prospered because the early members “were all of the aristocratic, paternalistic class prevalent in much of the South at that period.” Many of them had received their formal education abroad and sent their sons and daughters abroad for education. There were weekly meetings to which members came, usually 20 to 30. A part of the income of the society was invested in bonds, with the result that by 1775, the funds amounted to £18,000. With sophisticated, well-educated members, the library emphasized the classics and had a fine collection of classical literature. It suffered some from the occupation of Charleston by British troops during the Revolution but was largely destroyed by a major fire. It continued for some years as a social club, and then in 1790, it was reorganized with the remaining books as part of its collections.^[17,20]

Shortly after the successful beginning of Franklin’s Library Company of Philadelphia, subscription libraries of varying sizes began to proliferate in the middle colonies and particularly in New England. Prior to the Revolutionary War, however, there were only two or three in the South.^[20] The social libraries, like the parochial libraries

that preceded them, filled a need in the colonies, which were beginning to expand in population. Their collections were quite different, with less emphasis upon religion and more upon secular matters of concern: history, biography, travel, poetry, grammar and rhetoric, agriculture, arithmetic, and natural science are examples of the areas of more prevalent works. Shera suggested that the year 1790 was the midpoint in the effective life of the social library, with its period of most vigorous activity from 1790 to 1815 and a gradual decline from 1815 to 1850.^[13] Like most social agencies, the social library suffered in periods of economic decline. The social library declined largely as a result of a number of factors of which the rise of the public library was but one. For one thing, it could not "meet the expanding demand for library resources"; it was restrictive, that is, its clientele was limited at a time when the movement toward popular education was becoming strong. It made a major contribution to the library movement:

Almost from the very beginning the social library movement assumed the central attributes of a public library system. . . . By virtue of the implications for the future, as well as of the character of its past, the social library is an important factor in the evolution of the modern public library.^[13]

A strictly commercial library was the circulating library, perhaps more accurately, a collection of books gathered together for those who wanted them for home use. And the intent of the proprietor was profit. He was more likely than not to cater to popular taste and to avoid concentrating on "good literature." Quite often, circulating libraries were operated in conjunction with bookstores. Although they had been in existence on the Continent and in England much earlier, these libraries became active in the latter half of the eighteenth century in America. One of the earliest, that of William Rind of Annapolis, opened in the fall of 1762. This library and many of those that followed it had a relatively short life. One of the major problems was that of relending on the part of patrons, a practice that deprived the proprietor of needed revenue. It was necessary, too, for the circulating library to anticipate and keep up with the more ephemeral materials. A major criticism of this form of library was that it relied heavily on fiction, "a discredited literary form."^[13]

Other types of libraries rose to fill a need for books prior to the appearance of the public library. While rather similar in character, they were known variously as mercantile libraries, mechanics' libraries, young men's libraries, and apprentices' libraries. These libraries were closely related to the growth of the education movement in the first half of the nineteenth century. Mechanics and apprentices turned to libraries for satisfaction of their need for education, and the form of library they used was a

modification of the social library.^[13] In England at the turn of the century, workers' institutes devoted to the "intellectual development" of the workers appeared with emphasis upon science in the beginning but expanding later to include literature, history, and the arts. There were libraries, lectures, and discussions as part of their programs. The movement was extensive in England and spread to America.^[13] Most of such libraries in America, according to F.B. Perkins, had an education department or school as a principal activity. Classes were offered in bookkeeping, arithmetic, writing, and language. Some also had, in addition to a reading room, a game or chess room, and in some instances, a gymnasium. Perkins further suggested that they were "planned rather like a sort of business college, as if to furnish a general higher education to those who were not able to go as far as desirable at school."^[21] Their collections, he reported, varied, were "founded on old and solid libraries," and were "of much positive value." Most were, however, "to a predominating extent. . . as they must necessarily be, collections of popular literature." Like most other libraries of their era, there was a major lack of money. They overcame a part of their difficulty by bringing in a group of older men whose concern was control of the property interests of the group.^[21]

Mercantile libraries, "as distinct from other social libraries. . . may be described as primarily for the use of merchants' clerks; secondarily, also, for all general readers."^[21] More specifically, they were intended to satisfy the reading requirements of the merchants' clerks and were supported in part by merchants and a periodic fee. They differed from mechanics' and apprentices' libraries in that they began as libraries; their educational aspects came later. There was also a greater emphasis not only on business-related areas but upon history and literature.^[13]

Still another type of library providing books primarily to young men and artisans, but to others as well, was the YMCA Library. The first Young Men's Christian Association in America was founded in Boston in 1851, "for the improvement of the spiritual and mental condition of young men." The YMCA Libraries, therefore, developed in the period when the "public" library, as exemplified by the Boston Public Library, was emerging. By 1859, there were 145 associations with libraries, 12 of which had 1000 or more volumes. In 1875, it was calculated that there were 478 associations with an aggregate membership of 43,612; of these associations, 180 reported having libraries, with a total of 164,188 volumes. The largest of these libraries was said to be that in Washington, with a collection of about 15,000 books. Like the mercantile, mechanics', and apprentices' libraries, they also had lectures. In the larger towns, the YMCA was apt to have classes in "those branches of practical knowledge which are especially available in business pursuits." In many towns, the only library "open to the public" was that of the Young Men's Christian Association. The reading rooms "are always free to the general public." An effort was made to

have the libraries open “at hours when they will be conveniently accessible to the young men of the community.” Occasionally, they were open on Sunday. The library in New York was reputed to have the best collection. The information in Table 1 indicates its breadth.

The libraries described in the preceding paragraphs served as forerunners of the tax-supported library that provided free access to all comers. They provided access to books for several levels of society, when in most cases, there would otherwise have been little access to them. While the social library was still in the ascendant, the first moves toward the public library were made.^[22,23]

Caleb Bingham, a Boston bookseller and publisher, in 1803 made a donation of 150 titles to his native town of Salisbury, Connecticut, to serve as a library that would provide reading he did not have as a boy. A self-perpetuating Board of Trustees was to have control of the Bingham Library for Youth, open “freely” to those between 9 and 16 years of age. The library was accepted gratefully by the town, which appropriated \$100 for the purchase of “suitable books.” Such support continued fitfully for years, and then the library was entirely neglected until it was absorbed toward the end of the century by the Salisbury Library Association, which became the Scoville Memorial Library Association.^[13]

The town of Lexington, Massachusetts, also had a library, funds for which were appropriated in 1827. By 1839, however, the town discontinued its periodic payments for support. Shera suggested that a pattern had begun to emerge, that municipal support had been given to these two libraries, and that the next step was “institutional permanence and stability” for the public library derived from municipal support. This came with the establishment of the Peterborough Library in 1833.^[13]

In 1835, New York State passed legislation that permitted the levying of a tax to support school district libraries. Other states followed, but by 1876, the impetus was lost. Oliver Garceau credited their decline to the fact that they were artificially created by state planners, following no local pattern of cultural loyalties; they served too small an area—in New York, only 267 persons to the district; they were inadequately housed, poorly supervised by school trustees, and badly managed by elected librarians.^[24]

In Indiana, an attempt was made to set up county libraries under the constitution of 1816. Because of the frontier conditions, it failed.

The first large municipality to establish a library that met the requirements of a modern public library was Boston, which opened the doors of its library to the public on March 20, 1854. The concept of a public library for Boston had been suggested in a letter written by George Ticknor, Smith Professor of the French and Spanish Languages at Harvard, to Daniel Webster in 1826, 7 years before the Peterborough Library was established. Ticknor, a trustee of the Boston Athenaeum—once called a public library by Charles Coffin Jewett (“practically it is such”)—wrote that he had a project to join all of the libraries of Boston, including the Athenaeum, into “one establishment.” He would let “the whole circulate.” He envisioned elimination of duplication of books, of quarters, and of librarians and their salaries. With the money saved, he would buy more books. Nothing came of the proposal.^[25] Suggestions as to combining the libraries of Boston into one large unit also came from a Frenchman, Alexandre Vattemare, a ventriloquist whose stage name was M. Alexandre. Vattemare had visions of bringing peoples closer together by an international exchange of books—as had the Reverend Brown’s associates before him.^[9] He appeared in New York in 1839 and over the next 2 years he advocated his plan during his various appearances in the United States and Canada. In Boston in 1841, he interested a group of young men who used the Boston Mercantile Library and several prominent citizens, notably, Charles Francis Adams. No project materialized, but there was an exchange of gift books between Vattemare in Paris and the City of Boston. One of the gifts, a rather handsome one of nearly 100 volumes, led to the appointment by the City Council of a Select Committee to recommend a suitable return gift and a place where the gift books should be kept. The committee recommended a room in City Hall. It also included the recommendation that there be established a public library and advised that an anonymous donor (Mayor Quincy) was offering \$5000 toward the project with the proviso that \$10,000 for the purpose be raised “at large.” The library was to be “fully used by all, as may be consistent with the safe-keeping of the property.” As a result of this proposal, the council in November 1847 appointed the Joint Special Committee on the Public Library, which among other charges, was to consider the feasibility of applying to the legislature for the authority to establish and operate a public library. In early 1848, a new City Council directed the mayor to apply to the legislature for such authorization, which resulted in an act authorizing the City of Boston to establish and maintain a public library. The governor of Massachusetts signed the act on March 18, 1848.^[25] A prime force in the progress toward the establishment of the library was the zeal of Mayor Josiah Quincy. Also important in the movement were

Table 1 Holdings of New York YMCA library.

George Ticknor, Edward Everett, and Mayor Joseph Bigelow, who followed Josiah Quincy as mayor in 1849. Quincy, treasurer of the Boston Athenaeum, naturally favored joining the two libraries. The Athenaeum had been established in 1805, an outgrowth of the Anthology Society organized to continue publication of the *Monthly Anthology and Boston Review*, about to go out of existence. The next step was an Anthology Reading Room and Library, a subscription to which would cost \$10 per annum. Soon there were 160 subscribers. When the library opened on January 1, 1807, there were more than 1000 volumes and English, French, and American periodicals.^[15] The Athenaeum grew and prospered, although it was in some difficulty in mid-century because of unanticipated costs in the construction of its new building. The proposal to join the two libraries fared well until it was put to the proprietors for approval. The proprietors postponed the matter indefinitely, and the Public Library proceeded on its own.^[25]

The library began operation by opening to the public the first of its two rooms in the Mason Street Schoolhouse on March 20, 1854. It was open daily (except Sunday) from 9:00 A.M. to 9:30 P.M. and all “inhabitants” of Boston over 16 years of age might use it. A single volume might be withdrawn for home use for 14 days on signature and agreement to observe library rules by a select list of people including, among others, city officials and employees, ordained ministers, teachers in private schools, and benefactors (contributors of \$100 or more). Other inhabitants of Boston who wished to borrow a book had to deposit the full value of the book with the librarian.^[25] The first librarian appointed by the council, Edward Capen, was a Harvard M.A. who later became a graduate of Harvard Divinity School, and who had served as a clergyman for several years. He was appointed in May 1852. While he was still serving as librarian, the council at the behest of the trustees appointed a superintendent who would have the general responsibilities of administration. The appointment was an annual one, and the position might remain vacant by decision of the council or by the trustees’ decision not to make a nomination. The first appointee was Charles Coffin Jewett, who served from 1858 until his death a decade later. Jewett had been librarian of the Smithsonian Institution in Washington and had come to Boston to work with the books received through the munificence of Joshua Bates. For that purpose, the trustees rented a house on Boyleston Place in 1855, wherein Jewett was installed.^[25] Joshua Bates, a poor boy of Boston who grew up with nothing to spend on books, had the good fortune to be able to satisfy his great desire to read in the bookstore of Hastings, Ethridge, and Bliss, after his long work hours in a counting house. Remembering his own lack, Bates, who was senior partner of the London Banking House of Baring Brothers and Company, offered the sum of \$50,000 for books. When the council put a new building under construction, Joshua Bates offered a

second gift, the purchase of a “considerable” number of books to be held in trust for the new quarters so that when they opened there would be an adequate number on hand. He estimated the cost would run \$20,000 to \$30,000. It was this latter gift that Jewett was hired to prepare (in the temporary quarters on Boyleston Place) for use in the new building.^[25]

Under Jewett’s administration, the library made substantial progress. The library had moved into its new building on Boyleston Street on New Year’s Day, 1858, and Jewett became its new superintendent almost immediately. On Jewett’s death, January 8, 1868, he was succeeded by a trustee, Justin Winsor, under whom the library continued to progress. When he resigned and became librarian of Harvard in July 1877, it was an outstanding library.^[25] By 1868, it had a collection of 144,000 volumes and 50,000 pamphlets, second then only to the Library of Congress, which had 175,000 volumes and 70,000 pamphlets. At that time, Winsor noted that only two other public libraries had fairly sizable collections: New Bedford, 21,000 volumes; Cincinnati, 20,000. He noted that Liverpool, the largest of the English public libraries supported by the penny rate, had 84,000 volumes. By 1877, too, there were six branches, several stations, and regular deliveries of books to 13 firehouses and a fireboat.

The motives of those who were largely instrumental in the founding of the Boston Public Library and libraries in larger cities have come under question. Michael Harris, in an article entitled the “Purpose of the American Public Library,” attacked what he called the comfortable concept, widely held, that the public library movement was “launched in the 1850’s by an intelligent middle class led by a group of enlightened civic leaders.” George Ticknor is seen as insisting that the public library should be “dedicated to the continuing education of the ‘common man.’” Actually, public libraries, Harris argued, were always “generally cold, rigidly inflexible and elitist institutions.” He makes a strong case to support his contention that the founders were men of substance, conservative, and dedicated to the preservation of the form of the society they ruled over. The library, as they saw it, would help educate the new residents of the city, for they were not capable of understanding the country’s free institutions. They would be brought “in willing subjection to our own institutions.” Harris continued with the concept that those who were hired to run the libraries were “technicians” who were “dedicated” to the founders’ concept of the library. Carnegie, when he appeared, was equally authoritarian in his approach to the founding of libraries, and he saw them as a means of helping persons to help themselves, to “make men not violent revolutionists, but cautious evolutionists; not destroyers, but careful improvers.”^[26] Harris further saw librarians as moving the public library in the first half of the twentieth century toward assuming the role of a bastion of democracy “by assisting the successful working

of self government.”^[26] The library would do so by providing information on both sides of a subject. The user would decide for himself, and the librarians’ traditional “passivity” would not be brought into question. Harris’s “revisionist interpretation” has not gone unchallenged. Phyllis Dain in her article “Ambivalence and Paradox” pointed out that Ticknor was “aristocratic and conservative” and that his choice of the public library as a means to open opportunities to people, rather than to close them, was “an expression of the 18th century rationalists’ faith that the lower classes could be integrated into society through education.”^[27] She also pointed out that in view of the urban masses’ lack of leisure time, lack of access to those who controlled the money, and low level of education, none but an “elite group” was left to foster the public library. As noted earlier, there were many other forms of libraries—mercantile, apprentices’, mechanics’—supported in part and used by groups who were not elitist. Phyllis Dain also challenged Harris’s criticism that librarians had become technicians and bureaucrats. The increase in numbers of libraries, size of collections, and in staff naturally led librarians to “rationalize procedures and bureaucratize personnel.”^[27] The Harris thesis, too, does not account for the large numbers of public libraries established in modest-sized towns that lacked urban poor. It might be noted in passing that in England, there were in Parliament members of the “elitist” group who “almost feared that these libraries might be converted into normal schools of agitation.”

The public library movement in the latter part of the nineteenth century was stimulated by the philanthropy of many who had made their fortunes in America’s burgeoning industries. One very early benefactor was John Jacob Astor, who in a codicil to his will, in August 1839, set aside \$400,000 for the establishment of a public library. He was directed toward this philanthropic move by Joseph Green Cogswell, who subsequently (at Astor’s request) moved in with him and spent some years prior to Astor’s death in 1848 in buying books, preparing catalogs, and seeing to it that the benefactor did not change his mind about his bequest. He helped plan the building and served as superintendent of the library from its establishment until 1861 and as a trustee until 1864. Cogswell thought of the Astor Library as a reference library and primarily for those engaged in research. No circulation was permitted. Its hours were short and access difficult. As a result, it enjoyed a poor press, and complaints were widespread. Members of the Astor family continued to contribute to the library for some years, so that it was able to grow and to achieve preeminence. From 1876 to 1894, however, “it had lost its pre-eminent position and slipped into somnolence.”^[28,29] James Lenox, a wealthy and prominent New Yorker, founded a second reference library in New York City. The founder, a merchant and large property owner, was a bibliophile who gathered a fine library of 20,000 volumes, which in 1870, he had incorporated into a public

library. If anything, it enjoyed an even poorer reputation as a public institution than the Astor Library. It was some years after its establishment before it was finally opened to the public. Because of its great treasures and the fear of its founder that they would be lost or vandalized, access was limited. Further, “stress was placed not on use of materials but on viewing them.”^[29] A third major bequest for the establishment of a library was that contained in the will of Samuel J. Tilden, which placed the largest part of his estate, \$5,000,000, in the Tilden Trust. Tilden, a successful lawyer, had established his reputation by prosecuting successfully the Tweed Ring. He had run on the Democratic ticket for the presidency of the United States in 1876 but lost the election in the recount of votes made in three southern states. The trust was attacked by members of the family, nieces and nephews. Although the court suit went against the trust, there was eventually an agreement to partition the estate, which provided the trust with something between \$2 and \$2½ million. In 1895, the two libraries, Astor and Lenox, were merged with the Tilden Trust to create the New York Public Library. The first director was John Shaw Billings under “whose forceful leadership they [the trustees] saw the New York Public Library built almost overnight into the illustrious institution of their ambitions.”^[29] The library created in 1895 was a reference library. The circulation function was achieved when an agreement of consolidation was completed with the New York Free Circulating Library, January 8, 1901. The Free Circulating Library, incorporated in 1880, was the outgrowth of the efforts of the teachers of a sewing class in Grace Church who wished to raise the reading level of the children. As interest grew in the project and more women became involved, a reading room was provided for the 500 books collected. The project expanded, was incorporated, and at the time of the consolidation, the library possessed some \$300,000 in cash and securities and five buildings (valued at \$300,000) and operated 11 branches with 160,000 books that accounted for an annual circulation of 1,600,000.^[28]

In Baltimore, Enoch Pratt, a successful merchant and investor and a native of New England, presented the city in 1882 with a sum of \$1,058,333.33 for a library, provided the city would agree to create an annuity that would provide \$50,000 per annum. The gift consisted of a building already under construction that would cost \$225,000 and “upon its completion, the additional sum of eight hundred and thirty-three thousand three hundred and thirty-three and one-third dollars.” The library grew rapidly, and in a decade, had a collection of 150,000 volumes and five branches. Andrew Carnegie in 1905 offered \$500,000 with which to build 20 branch libraries. The branches were built over a period of years. The City of Baltimore, too, began adding money each year to supplement the annuity’s yield as operations expanded and expenses rose. Much of the later success of this library may be attributed to Joseph L. Wheeler, who became its

director in 1926; he was an outstanding administrator who later became a sought-after library building and management consultant.^[30]

Many libraries, some quite large and others designed to serve relatively small towns, were established by gifts of wealthy men and women in the next few decades. The major benefactor of libraries, of course, was Andrew Carnegie. Born in Dunfermline, Scotland, in 1835, he came when a boy (1846) to the United States with his parents, who settled in Allegheny, Pennsylvania, a city across the Allegheny River from Pittsburgh. Successively a bobbin boy in a cotton mill, a telegraph messenger, a telegrapher, and a section superintendent for the Pennsylvania Railroad, he began to invest his money in profitable projects and then entered the iron and steel business. From his various sources of income, Carnegie amassed a huge fortune for the day. About 90% of that fortune went into various charitable and philanthropic projects—more than \$333,000,000.^[31] He donated \$56,162,622 to construct 2509 library buildings in the English-speaking world. Except for a few instances, Carnegie donated money only for buildings and did not support or endow libraries. The support of the building by the municipality was a stipulation required before the grant was made. In America, he provided \$41,033,850 to construct 1412 buildings.^[31] With the library acting as his agent, he entered into an agreement with New York City on July 17, 1901, to provide the city with funds to acquire in the boroughs of Manhattan, Bronx, and Richmond “not more than 42 [later raised to 50] library sites” and erect buildings on them. Earlier, Carnegie had made a contribution to the Free Circulating Library.

The Carnegie library grants were given between the years 1886 and 1919. The bulk of the gifts were made in what he called the “wholesale” period, 1898–1919, to libraries in 1406 communities in the amount of \$39,172,981.^[31]

At the time of publication of the Bureau of Education’s Special Report, *Public Libraries in the United States of America* (1876), the editors were able to include a “Table of public libraries numbering 300 volumes and upwards” which included 3649 libraries. The majority of those listed were university, college, academy, public school, mercantile, and social, and were not municipally supported. There was a fair sprinkling of libraries bearing the title “public library.” In 1890, however, of America’s 16 largest cities, only seven had municipally supported central libraries.^[27] The period of the Carnegie gifts changed this situation markedly. Not only did his gifts account for more than 1400 library buildings, but they stimulated communities that had avoided applying to Carnegie initially to provide libraries on their own at a later date. Libraries had spread over the United States in increasing numbers as the last decades of the nineteenth century were reached, but the major growth came after the Carnegie period.

The growth of the public library movement was slowed somewhat by the great depression of the 1930s. As with many other public agencies, the libraries found themselves with shrinking appropriations and revenues but with increasing use. Library adult book circulation, particularly nonfiction, was up. Total expenditures were down, but expenditures for books dropped relatively more than did salary expenditures. Two of the economic factors that explain increased use of the public library are unemployment and the reduced earnings of those employed.^[32]

During World War II, a definite move toward improved public library service in the years to follow the close of hostilities was the *Postwar Standards for Public Libraries* (1943), followed in 1948 by the publication of *A National Plan for Public Library Service* prepared for the Committee on Postwar Planning of the American Library Association by Carleton B. Joeckel and Amy Winslow. In 1950 came the Public Library Inquiry, which was designed to be “a thorough and comprehensive study of the American free public library.”

By 1956, the Coordinating Committee on the Revision of Public Library Standards, Public Libraries Division of the American Library Association, had produced *Public Library Service: A Guide to Evaluation with Minimum Standards*. The document was made up of principles and standards and covered subjects, books and nonbook materials, personnel, the organization and control of materials, and physical facilities. The *Standards*, as they came to be called, were criticized by some librarians as being goals rather than standards, for they were impossible to attain by most libraries. Other librarians complained that there were not enough “measurements” given. A supplementary publication subsequently provided such statistical measures for libraries in several categories by size. In 1967, the American Library Association published an updating of the *Standards* entitled *Minimum Standards for Public Library Systems, 1966*. This publication contained a number of finite standards as well as the principles and broad standards.

The 1956 *Standards* contained a statement that was to affect public library development for some years to come:

Libraries working together, sharing their services and materials, can meet the full needs of their users. *This co-operative approach on the part of libraries is the most important single recommendation of this document.* Without joint action, most American libraries will probably never be able to come up to the standard necessary to meet the needs of their constituencies.^[33]

Library systems were not new. They had developed out of county libraries at the turn of the century. In particular, they developed into county systems in California. By 1916 “thirty-seven of California’s fifty-eight counties were persuaded to establish libraries.”^[24] From the county system, it was but a small step to the multi-county library system

or regional library system. In 1969, the American Library Association (ALA) published a survey of systems. The system concept has become an integral part of most state public library plans, to which are being added networking and resource sharing. These techniques are being made more effective through the use of computer bibliographic data banks like the Ohio College Library Information Center (OCLC), which extends its service over a large part of the United States. Another benefit of OCLC is its classification and cataloging service.

Despite the efforts of the ALA to improve library service after the end of World War I and the efforts of its committees as noted above, there were still over 85 million Americans without adequate library service in mid-century, particularly in rural areas. In 1956, a U.S. Office of Education report revealed that 26 million rural residents were without any public library service. An additional 50 million rural residents had inadequate service. A strong effort with farm block support succeeded in passing the Library Service Act in that year (1956). It authorized the appropriation of \$7.5 million annually for 5 years. The funds were for “services” and were limited to rural areas (10,000 or less). No money was appropriated until 1957, when the Congress appropriated \$2,050,000. The next year it appropriated \$5 million, and \$6 million for each of the next 2 years.^[34] In 1961, the act was renewed for another 5 years, but in 1964, it was amended to become the Library Services and Construction Act. It contained two titles: I. Services; II. Construction. Funding was in the amounts of \$25 million and \$20 million, respectively, and the restriction of funds to rural areas was removed. The act again was amended to provide two additional titles in 1966: III. Interlibrary cooperation; IV-A. State Institutional Library Service, and IV-B. State Library Services to the Physically Handicapped. The act was renewed in 1970 and continued through fiscal year 1976. Title IV was joined with Title I, which resulted in some fear that both Title I activities and services to the handicapped might suffer if funds ran out.

The Library Services and Construction Act has generally been considered to have had a beneficial effect upon public library programs. It resulted in the institution of service to many unserved rural people, in service to the disadvantaged, in the upgrading of services at the state agency level, and in a great number of new library buildings. Federal funds were provided for demonstration projects that resulted in the provision of local funding for their continuation. One criticism levied at the program was that too much of the federal allotment in many states went into agency operational costs, to the detriment of libraries in need of support. Of particular importance was the money (relatively less than for other titles) awarded under Title III for cooperation between types of libraries.^[35] Out of early experiments have come “networking” and “resource sharing” that may well cut into duplication of materials, services, and costs.

Until the mid-1960s, funding for public libraries under the Library Services and Construction Act seemed to be growing at a rate quite satisfactory to librarians and their supporters. The amended act of 1966 projected a total authorization over the next 5 years of \$700 million for the four titles of the act. As the extent of the United States’ involvement in Southeast Asia became a major factor in the nation’s economic life and inflation increased accordingly, there was less funding available for social and educational programs at the national level. Table 2, covering fiscal years 1969, 1972, and 1973, indicates the changes that occurred.

The figures in Table 2, taken from *The Bowker Annual* for the years cited, do not tell the complete story, for funds could be and were impounded by executive order. To replace categorical funding such as LSCA, the president proposed in 1972 a new type of funding, revenue sharing, which provided funds for state and local governments over a 5-year period. These funds were to be spent for “priority expenditures,” which included libraries but placed them somewhat down the list of priorities. In many instances, local governments had other programs they preferred to fund, and some municipalities merely substituted revenue sharing funds for local funds they had been appropriating for libraries.

The public library in America in the 1960s and early 1970s moved actively to take materials and programs to the people who were not accustomed to coming to the library for them. More specifically, librarians were seeking ways to stimulate minority groups and others who did not have library use in their backgrounds to take advantage of and use library services. One major approach was “outreach,” taking programs and services to the inner city or wherever these persons might live. Reference and information services were greatly improved, and the library became responsive to the multimedia orientation of the country’s youth. The public library too, became actively involved in continuing education. It was suggested by one of the library’s strong supporters that it had “become the most economically effective educational institution evolved by mankind.” It served as the resource center for those enrolled in “external university” or “university without walls” courses, and for high school students preparing for the College Level Examination Program (CLEP).

Table 2 LSCA appropriations, 1969–1973.

Fiscal year	Title	Authorization (\$)	Appropriation (\$)
1969	I	55,000,000	35,000,000
	II	60,000,000	9,185,000
	III	10,000,000	2,281,000
1972	I	112,000,000	46,568,500
	II	80,000,000	9,500,000
	III	15,000,000	2,640,500
1973	I	117,600,000	30,000,000
	II	84,000,000	0
	III	15,750,000	2,640,500

Some of the larger city libraries, too, entered cooperatively into continuing education programs sponsored by nearby colleges and universities. For the individual proceeding on his own, it provided the source of information and materials for his self-education. Librarians enrolled in courses designed to train them to work with patrons who wished to retrain themselves or raise the level of their knowledge. The public library thus provided information, books, and nonbook materials supportive of individual and group educational efforts.

CONCLUSION

As the public library approached the last quarter of the twentieth century, it was beset with a number of difficult problems. The principal one continued to be that of adequate financial support. Urban libraries, particularly those in the older cities of the Northeast and Midwest, were suffering from the effects of urban blight, the flight to the suburbs, and sharply increasing expenses of operations. The library, a part of municipal government that unfortunately did not command as high a priority as some other functions, was forced in many instances to close some branch operations and curtail the hours of opening at the main building. To cope with these problems and to pressure for federal support, the Urban Library Council, made up of the librarians of nearly 50 major urban libraries, was formed. Despite what seemed to be a rather dark picture, a number of cities have managed to keep the library operation on a fairly even level and, in some instances, to float bond issues to construct new main libraries and branches. During the year 1976, there were 277 public library construction projects completed, of which 90 were building alterations. The total expenditure for the projects was \$66,374,466, with the majority of this construction for medium-sized and small buildings. Most librarians who considered the problems of administration and who wrote of their reactions were not pessimistic about the future.

History of Records and Information Management

William Benedon

Benedon & Associates, Encino, California, U.S.A.

Abstract

Records management is the information management discipline that addresses the “life cycle” or “birth-to-death” concept of records and the information they contain. It includes the principles and practices that cover the creation, processing, storage, retrieval, protection, and final disposition of records. Records management also evaluates the administrative, financial, legal, operational, and historical need for records. These principles and practices apply to all records, regardless of media, and have been of significant value as business and government transactions have moved from paper, to micrographic, to electronic format. This entry presents an historical overview of the discipline, the factors that brought it into being, the events and individuals that contributed to its development, acceptance, and use as a valuable management tool.

INTRODUCTION

One of the major problems facing business, industry, and government today is how to most effectively and economically manage and utilize a continually expanding accumulation of information. Technological and social changes have resulted in the creation and dissemination of an endless volume of data in a wide variety of records formats. While much of the information demanded and produced is needed, there is also a proliferation of useless and duplicated materials. The object of an organized approach to the management of information must have two principal goals—first, to obtain the maximum value from all information disciplines and second, to obtain that value in an orderly, productive, and cost-effective manner.

Information management is the process of identifying and utilizing all of the information disciplines and information resources enterprise-wide to achieve efficient, effective, and competitive management decisions. Records Management is an information management discipline that involves the principles and practices used by an organization to properly manage its records from their creation to final disposition. A record is recorded information, regardless of medium or characteristic, made or received by an organization that is evidence of its operations and has value requiring its retention for a specified period of time. Since it deals with the information content of records as well, the discipline is popularly referred to as records and information management (RIM). Records management has also been identified as the “life cycle” or the “birth-to-death” concept of records and includes such elements as

- Forms/reports management—The establishment of procedures for the control and design of forms and reports needed in the processing of transactions and summarization of data. This program may also include directive and manual preparation.
- Correspondence management—Assuring the proper preparation, routing, and control of internal and external communication.
- Filing systems—Evaluating and selecting the best type of filing and indexing system to be used as well as the equipment being considered for housing records.
- Retention scheduling—The physical flow requirements of records and their value at each action location (office, storage, and final disposition). The term “records retention or control schedule” is preferred to “disposition schedule.” This avoids concern that the program is being used primarily for throwing out records.
- Records centers—The establishment and use of central repositories, as may be required, for the low-cost housing of inactive, vital, and archival records, and to maintain such repositories in an orderly, efficient, and economical manner. Such facilities may be operated in-house or outsourced to commercial companies specializing in the records storage business.
- Records protection—Providing records classifications, procedures, and facilities necessary for the protection of records needed to continue or resume business following a disaster.
- Image management—Making effective use of image processing technologies (micrographics, optical disk, and the like) for the handling, processing, protection, and retention of records.
- Archives management—Providing for the continuing evaluation and preservation of records having historical value and to assure their proper housing and indexing.
- Information technology—Carefully reviewing new technologies that impact on the manner in which businesses use such technologies to manage their records and assuring the proper administrative and legal uses of such technologies.

The past 50 years have produced significant technological developments in the information and records management field. The above principles are applicable regardless of media being used. The first major transition came from the application of microfilm for replacing paper copies. It had two primary values as a replacement for storing paper records and for duplicating vital records. It was hailed as the panacea for reducing the volume of stored records. This quality disappeared as the use of low-cost records centers proved to be a more cost-effective approach. This competitive element shifted the focus of microfilm to systems applications and brought about its major value in the form of computer output microfilm (COM)—a system of converting computer output to microfilm, computer-assisted retrieval (CAR)—rapid retrieval of information on microfilm, and computer output to laser disk (COLD). Further advances included optical disks, bar coding systems [upgraded to radio-frequency identification (RFID)]. All became part of the computerization age and the birth of the electronic record.

Records management has proven to be of particular value when applied to electronic records. An *electronic record* is a record created, generated, sent, communicated, received, or stored by electronic means. Usually the term applies to all electronic records systems, whether in microcomputers, minicomputers, or mainframe computers, regardless of storage media, in networked or stand-alone systems, including small computers, such as memory typewriters, calculators, and embedded systems. Examples include records stored on a server, or on magnetic media, such as tapes, disk packs, compact disks, or optical disks.

Electronic records keeping or *electronic records management* is the use of records management principles for records maintained electronically. An *electronic record keeping system* (ERS) is primarily a software-based methodology used by an organization to manage all its records, regardless of format, over the entire record's life cycle. Primary records keeping functions of these systems must include categorizing, locating, identifying, and controlling record disposition requirements, including management of the storage, retrieval, protection, and disposition of the records regardless of repository.

BEGINNING OF MODERN RECORDS MANAGEMENT

Records management is an outgrowth of archives management and is concerned with the need to preserve records that have long term or permanent value. The rapid growth of business, government, and industry resulted in a significant growth in the amount of documentation needed to manage and operate such activities. This growth resulted in an uncontrollable amount of records, with related administrative costs. Records management has provided

the principles and practices needed to properly balance the cost of providing needed records and their retrieval and maintenance costs.

Following World War II, President Harry Truman established the *Commission on the Reorganization of the Federal Government* to address the many operating issues of the U.S. Government resulting from its growth and expansion from the war years. Former president Herbert Hoover was named head of the commission (thus the popular name Hoover Commission). One of the Task Forces under the commission was given the responsibility for examining the government paperwork growth and to recommend methods for its management. Emmett Leahy (a former member of the National Archives and responsible for organizing the records of the Navy Department and a private consultant following his government career) was named chairman of the Paperwork Task Force. The study results were significant. They applied the previously mentioned elements of records management to government paperwork activities with a significant reference to cost savings. Although the term “paperwork management” was used in the report, the term was soon broadened to “records management” to address all records media. These actions were the beginning of records management as it is practiced today.

Two major legislative acts resulted from the Hoover Commission efforts. The Federal Property and Administrative Services Act of 1949 transferred the National Archives to the newly created General Services Agency. The name, National Archives, was changed to the National Archives and Records Services (NARS) to reflect its responsibility for current records as well as archival records. The Federal Records Act of 1950 defined “records management,” further clarified and expanded the records management role of NARS (requiring each agency to establish an active and ongoing records management program), and NARS began establishing a series of records centers to store semi-active federal records. NARS remained part of the General Services Agency until 1985, when, through the efforts of the then archivist Robert M. Warner, the National Archives again attained independent status as an agency and became known as the National Archives and Records Administration (NARA).

Emmett Leahy

Emmett Leahy was the leading figure in the introduction of the concept of “modern records management.” He joined the staff of the National Archives in 1935 as a Special Examiner to inspect records classified as “useless records” in agency lists. Such records could be destroyed or otherwise disposed of because they had no “permanent value or historical interest.” He soon determined that the federal agencies had no systematic means of identifying records of permanent value and the only way to address this issue was involvement in the creation and filing of

records. This would provide a process for segregating records of temporary value from those of permanent value. Emmett Leahy became a principal leader in the emerging government records administration program.

In 1941 Leahy left the National Archives to become the Director of Records Coordination for the Navy in the Office of the Secretary of the Navy. In that position he established a model records management program that introduced new records management concepts and techniques similar to those defining records management at the beginning of this entry. In this position he installed the first centralized records centers in the world for the storage of inactive Navy records. In 1945, with World War II coming to an end, he decided to join the civilian market and accepted the position of National Sales Manager in the Microfilm Division of Remington Rand. He left Remington Rand in 1947 to form the National Records Management Council (NAREMCO), a nonprofit records management consulting company, and the Leahy Business Archives, the first commercial records center in the United States. Based upon his experiences with the navy records centers, the records center's principal equipment was standard sized cardboard containers housed on steel shelving. The container was 10" × 12" × 15". Referred to as the "cubic foot" box it could accommodate legal as well as letter-sized documents. It is to this day the main storage container used in records center operations, both in-house and in commercial repositories. It was in this capacity, as a private consultant, that he was named chairman of the task force on records management for the Hoover Commission. In 1953, he left NAREMCO and formed Leahy & Co., a consulting firm, which also included the Leahy Business Archives, Inc.

Emmett Leahy died on June 23, 1964. An award in his name was established and sponsored in 1968 by Rodd Exelbert, then Editor and Publisher of the *Information and Records Management Journal*, and Leahy & Co. It is currently underwritten by the Huron Consulting Company and is presented annually by the Institute of Certified Record Managers. It is considered to be the most prestigious award given in the RIM field today. The Web site devoted to the Leahy Award (<http://www.leahyaward.com>) includes comments made by peers of Emmett Leahy that provide a personal insight into his influence in the development of the records management profession. The 1968 recipient of the award and author of this entry provided the following comments.

I was teaching junior–senior high school in the 1947–1950 period and taking my master's degree at NYU in accounting and foreign trade. I selected as my thesis "The Preservation of Accounting Records" (I don't really know why). I felt I didn't really want to be an accountant but I wondered what such practitioners did with all their records. Bob Schiff, a senior officer in the National Records Management Council (NAREMCO) was teaching at NYU at the time, had read my thesis, *Preservation of Accounting*

Records and suggested I make an appointment to meet Ed Leahy, president of NAREMCO and discuss a fellowship with the organization. Thus started a long and happy career in records management, but the real inspiration was my first meeting with Ed Leahy.

I was impressed the moment I met him. He had an exciting gleam in his eyes, an award winning smile, and an air of dignity and knowledge. He immediately put me at ease with his relaxing approach to talking about me and my interests with his personal anecdotes injected as we went along. From that day forward I felt the confidence to make a mark in the records management profession. At the time Ed Leahy also operated the Leahy Business Archives (the first commercial records center system) and I spent the first six months as a records center clerk in that operation. Then I quickly graduated to consulting analyst and worked on projects at Union Carbide, Monsanto Chemical, the City of New York, Oneida Knitting Mills, and Mine Safety Appliances (my first solo operation). While I had the opportunity to work with such notables as Bob Schiff, Bob Weil, and Art Barken, Ed was always available for comments and concerns. He had a practice of taking his analysts out to lunch when they were in town at his favorite Irish restaurant on 23rd Street in New York. The purpose of such get-togethers was to make us feel a part of a great adventure into this exciting world of records management.

I had the opportunity to attend many of Ed Leahy's speeches and accompany him on visits to company president's offices to talk about impending projects. Each trip was a learning experience and critiques that followed these meetings left long-range values for individual growth. I was continually impressed with his ease of presentation and ability to sell his ideas to all levels of management. I remember his telling me that 80% of records management was salesmanship, making certain your clients felt at ease by listening to them and taking their ideas into account. Salesman extraordinaire, you bet, and only in the most positive manner.

With Ed Leahy as a mentor, success was guaranteed. He had the dedication, the personality, and the knowledge to inspire confidence and commitment. What better advocate could there have been to address the records management needs of business, government and industry.

Professional organizations today grant a series of awards for records management based upon government and business program accomplishments, individual accomplishments, and literary awards. The Records Management Association of Australasia sponsors the J. Eddis Linton Award for the individual they consider to be the "father of records management" in Australia. Early in his career Eddis Linton formulated ideas about the need to manage business records in an organized and systematic way. He developed and implemented these ideas incorporating keyword filing systems, inactive records storage, and micrographic systems long before they became mainstream practices. "Fellow" designations are also granted

by records and archival management organizations to individuals making major contribution to the profession.

ACHIEVING RECOGNITION

The Hoover Commission Paperwork Task Force study resulted in the disposition of a significant amount of government records and clearly demonstrated the operating efficiencies possible through proper records administration. The results of studies subsequently conducted by Emmett Leahy through his consulting efforts showed similar results could be achieved in business. Through the development of retention schedules based upon careful value analysis, 30% of the records maintained by an organization could be destroyed, 30% could be transferred to low-cost records center facilities due to their reduced activity, and the balance would represent the currently needed and referenced records. Although these figures only represented one facet of records management (proper appraisal of records) they became the driving force for total records programs.

Many of the staff people from the NAREMCO took lead records management positions in government and business (Bethlehem Steel, State of New Jersey, Lockheed Corporation, IBM). The NARA, by virtue of the Hoover Study and the legislation that followed, began extending its program to government agencies and publishing training aids for records programs. Its publications, although directed to governmental operations, have been applicable to the private sector and it is one of the prime resources for all aspects of the subject. Under the able leadership of Everett O. Alldredge (Assistant Archivist for Records Management) and Herbert Angel (Assistant Archivist for Federal Records Centers), NARA took a major role in the development of the profession. One of its major contributions of this government agency in the early years of the professions was the preparation of an annual "Compendium of Federal Recordkeeping Requirements." This booklet covered all the records retention requirements by government agencies. It was organized by government department, described each record, and indicated the period of time the records had to be retained. Unfortunately, this valuable publication became the victim of one of the government's austerity programs. Private firms offering this information on a subscription update basis soon addressed the void. Another former government employee, Frank Knox, joined the commercial consulting world and introduced *Functional Forms Filing*, a system for analyzing business forms to assure better design for processing, to consolidate forms serving the same purpose, and to eliminate unnecessary forms.

Companies started to implement promotional programs to increase exposure to records management and to demonstrate the savings and efficiencies possible through a constant application of records management techniques.

They carried such names as "Operation Round File" (Northrup Aircraft), "Mile High File Pile" (Cleveland Electric Illuminating Company), and "Operation Trim" (Lockheed Corporation) and were further supported by a designated "National Records Management Weeks" [American Records Management Association (ARMA)]. Natural and man-made disasters, in the form of floods, earthquakes, and civil unrest, also put a major focus on records management as organizations became concerned about the need to assure business continuity in the event of a disaster.

Low-cost storage facilities, or records centers, modeled after those used in the U.S. government and the Leahy Business Archives, became a standard part of organizations' records programs. They were the first major part of records management outsourcing as commercial records centers started offering services for the storage, referencing, protection, and disposition of records. The increasing number of organizations providing such services resulted in the formation of the *Professional Records and Information Management, International Association* (PRISM) (<http://www.prismintl.org>). PRISM publishes an annual directory of its members' locations and services. There are independent non-PRISM member companies as well.

The NAREMCO had issued several reports on the impact the bombings in England during World War II had on the preservation of government and business records. This concern was further emphasized subsequently in the United States by the "Cold War," the "Cuban Crisis" situations, civil riots in Detroit, Michigan and Newark, New Jersey, the New York twin towers destruction, floods in North Dakota and Louisiana. Records protection programs identifying vital records needed to resume or continue business after a given disaster became a priority. Such programs have become an critical part of an overall records management programs.

Over the years, company and commercial facilities have been established to assure dispersal of backup records, including the use of abandoned railroad tunnels, underground limestone and mushroom caves, abandoned mines, and company facilities at company-owned locations remote from central business districts. The National Fire Protection Association (NFPA) in Quincy, Massachusetts (<http://www.nfpa.org>) issues a standard, NFPA 232, *Standard for the Protection of Records*. It primarily addresses the types of facilities that best serve to protect records. ARMA, International has also issued a standard covering vital records identification and management.

PROFESSIONAL ORGANIZATION GROWTH

For many years prior to the popular introduction of modern records management there had been several associations concerned primarily with the filing and maintenance of records. In 1955 several of these filing associations

(Chicago, Detroit, Minneapolis, Cleveland, Milwaukee, and New York), recognizing the broader professional impact of records management, formed the ARMA. Jack Britt, records manager for Ford Motor Company, was its principal organizer. The Britt Literary Award is presented annually by ARMA for the author of the article the association's magazine judged to be the best in terms of contribution to the field during a given publication year. The association was officially chartered in 1956 with headquarters in Detroit. A separate organization was also established at this time in New York. It was called the Association of Records Executives and Administrators (AREA). The main distinction was in the level of management authority held by the members. ARMA was open to all levels while AREA restricted its membership to the supervisory and managerial level. In 1975 the two organizations merged and became the Association of Records Managers and Administrators but retained the ARMA designation. Membership was open to all levels of practitioners in the field. In 1987, ARMA changed its logo to incorporate "International" in its name, becoming "ARMA, International." The association currently has a chapter in Japan and individual members in 30 countries around the world.

ARMA has had a rapid growth. From its original membership of approximately 375 it today numbers over 10,000. From the founding six filing associations (Filing Association of Chicago, Filing Association of Detroit, Filing Association of New York, etc.) there are currently in excess of 120 ARMA chapters in the United States and Canada in addition to individual members-at-large throughout the world. From an all volunteer operated organization, it progressed to a part-time executive secretary and then to a full time Executive Director with a paid staff headquartered in Lenexa, Kansas. ARMA has become the leading advocate of RIM, sponsoring national conferences and seminars, developing standards, monitoring legislation impacting records management, and providing technical reports on all aspects of the profession. It provides a continuing promotional program involving annual "Records and Information Management Week" utilizing posters and brochures for use by its chapters and by individual companies. It has undertaken special activities to highlight issues at hand. One notable example was the 1980 introduction of "Project ELF" (Eliminate Legal Files), aimed at reducing the paper and filing costs of legal-sized documents vs. letter-sized documents. This project had a positive impact on the filing procedures in many courts and businesses.

The National Association of Government Archivists and Records Administrators (NAGARA) was established as an independent group shortly after the formation of ARMA. Its membership is based solely on federal, state, and local practitioners in the field of archives and records management. It provides a member only quarterly publication covering issues restricted to governmental concerns.

The Association of Information and Image Management (AIIM), formerly the National Microfilm Association (NMA), also supports the records management concepts and provides materials on its website (<http://www.aiim.org>) and its *infonomics Magazine* (<http://www.infonomicsmag.com>). This organization retains the AIIM logo but is now referred to as the *enterprise content management (ECM) organization* ECM, like "re-engineering" and "knowledge management (KM), have been computer age terminology additions to processes for the effective use of information within an organization. AIIM works closely with ARMA on special studies, standards, and research efforts.

Other groups have been formed to address specialty areas concerns for RIM such as the Nuclear Information and Records Management Association (NIMRA) (<http://www.nirma.org>) and the American Medical Records Association. The latter changed its name in 1991 to American Health Information and Management Association (AHIMA) (<http://www.ahima.org>). The ARMA organization as part of its educational program also sponsors select groups addressing the interests of specialty fields in business and industry.

RECORDS MANAGEMENT TRAINING

This growing interest in the needs and benefits to be gained by the implementation of records programs by the private and government sectors led to the development of training programs and the establishment of forums to discuss and exchange ideas about the subject. From the mid-1950s to the mid-1980s, many leading universities started offering evening courses in records management. Introduced initially as special evening courses instructed by practitioners in the field, these courses became part of daytime curriculum. In 1964, the ARMA introduced the "Records Management Correspondence Course," authored and instructed by Mr. Benedon and administered by the association. This course was offered until 1985 when the ARMA national headquarters published its own version. This course was supplemented by one offered by North Dakota University in 1969. Many schools of higher learning offer records management courses today in their general business management, library sciences, and computer technology programs.

The first conference completely devoted to records management was held in New York in 1950 and sponsored by the NAREMCO. It introduced records management to a national audience and set the stage for annual conferences on information management. The American Management Association began a series of seminars in New York featuring speakers from companies that were embarking upon programs devoted to records management conferences. In 1956, the Visual Communications Congress, sponsored by the Society of Reproduction Engineers, and

the American Institute for Design and Drafting, added ARMA to its program roster. This group is no longer in operation. The ARMA, International organization has sponsored annual conferences since 1956.

PROFESSIONAL STATUS

A profession is recognized when it has developed a body of knowledge, a code of ethics, and a standard for measuring efficiency. ARMA and the other referenced associations have each contributed to the achievement of this recognition. As a professional measurement of these accomplishments and to officially measure the efficiency of practitioners in the RIM field, the Institute of Certified Records Managers (ICRM) was established in 1975 (<http://www.icrm.org>). Its initial Board consisted of the following representatives from ARMA and the former AREA organizations. Board member backgrounds covered business, government (local, state, and Federal), and education.

President:	William Rofes, IBM Corporation.
Vice	Col. Seymour J. Pomerenz, Department of the
President:	Army
Secretary:	Dr. L. Ruth Thomas, National Archives & Records Service
Treasurer:	Dr. Thornton W. Mitchell, State of North Carolina
Directors:	William Benedon, Lockheed Corporation
	Maj. Stanley Gordon, City of Los Angeles
	Mr. Dudley F. Judd, Exxon Corporation
	Mr. H. J. (Mark Koenig), Consultant
	Mrs. Katherine A. Mutchler, Lever Brothers Company
	Dr. Mary F. Robek, Eastern Michigan University

Following compliance with educational and experience requirements, and the successful completion of a six part examination administered by the Institute, one is granted the Certified Records Manager (CRM) status. The six part examination covers

Part I	Management Principles and the RIM Program
Part II	Records Creation and Use
Part III	Records Systems, Storage, and Retrieval.
Part IV	Records Appraisal, Retention, Protection, and Disposition
Part V	Technology, Equipment, and Supplies
Part VI	Case Studies

To assure continued professional competency, a maintenance program based on 5-year cycles is administered. Points are granted for continuing education, writings, presentations, or other professional activities. Training for the certification is provided through a study manual published by the Institute. This study manual also contains an excellent bibliography of reference materials for RIM. Special

examination study sessions are also presented during ARMA's annual conference and through ARMA chapter review programs. The examination can be taken at designated sites or online. The CRM examination is continually updated to reflect the latest applications of technology to the management of records.

The Institute has provided the professional basis for the recognition of records management, as an essential part of managing the information needs of business, government, and industry. Its examination is continually updated to reflect changes in technology and it addresses, as well, all information systems needs, regardless of media involved. Since the early 1990s ARMA attempted to add to this professional status by developing and defining the core competencies of RIM (knowledge, skills, characteristics, or traits that contribute to outstanding performance in a particular profession). This goal was achieved in 2007 with the publication "Records and Information Management Core Competencies." It is expected that this study will also impact on the content of courses being offered in RIM.

The NIRMA, with an additional section on nuclear operations, also uses the CRM certification exam.

LITERATURE

Professional recognition also comes from literary exposure. This availability of this needed resource is reflected in the rapid growth of publications that currently address the records management principles and practices. Prior to the 1950s there were several filing books published. These dealt mainly with filing principles and equipment since that was considered to be the main records maintenance requirement. The first book that covered records scheduling, records centers, and filing was published in 1963 and titled *Modern Records Management* and was authored by Emmett Leahy and Christopher Cameron. The first definitive text on records management addressing all the elements listed in the introduction to this entry was *Records Management* by William Benedon, published in 1969 by Prentice-Hall. From the mid-1970s on there have been several such texts.

The first technical study on records management, "Rules for Alphabetical Filing" was published by ARMA in 1960. This was followed in 1962 by the publication of the "Records Management Workshop" authored by William Benedon and adopted by ARMA as one of its publications. In the late 1970s ARMA expanded its own publication efforts through special studies and standards development and by marketing publications by individual authors. ARMA has a bookstore that provides an abundance of publications on the subject of records management. The bookstore can be accessed at <http://www.arma.org>.

ARMA's first official general publication for the profession was the "*Records Review*" introduced in 1960. This was an eight-page booklet covering articles on the subject and association news. In an effort to promote records management, the "*Review*" featured a mascot cartoon in the form of a clipboard with arms and legs and called *Scrappy*. This was the brainchild of Bernie Trumbull, a general records manager at Northwestern Bell Telephone Company of Omaha. *Scrappy* became a popular lapel pin for a period of time and was also used on promotional office supply items. In 1974, ARMA and its South Carolina chapter created "*Scrappy and Records Management*," an instructional video in five parts as an "in-house educational television training environment." ARMA upgraded the *Records Review* to a magazine *Records Management Quarterly* (RMQ) in 1967. This publication was renamed in 1999 (*The Information Management Journal*). Association news was dropped by the magazine and replaced by an insert, "News and Notes" and later "InfoPro" to highlight specific association issues and news. Inserts are now used solely for special studies or white papers. Prior to the merger of ARMA and AREA, the latter published the *Records Management Journal*. This publication was discontinued with the merger. In January 2009, ARMA dropped the word Journal from its magazines title. The only other magazine devoted strictly to records management was the trade journal, *Information and Records Management Journal* (IMJ), edited by Rodd Exelbert. This magazine is no longer published.

AN INTERNATIONAL CONCEPT

The initial interest in records on an international basis came from the archival community's interest in documents such as letters, official papers, photographs, or recorded materials kept for their historical interest. Individual country archival societies existed worldwide to address these interests. In 1948, through the efforts of then U.S. archivist, Solon J. Buck, the International Council on Archives (ICA) was formed. Current records were of secondary concern and referred to as just that—"current records." In 1976, the ICA formed a *Section on Records Management and Archival Professional Organizations* and has had cooperative efforts with records management organizations since that time. ICA has a global network of more than 1400 institutional members in 190 countries. It also has over 200 archivists and records managers as individual members. The records management and archival functions are closely linked today in both the public and private sector.

The traditional international archive community, mainly in Europe, did not initially recognize records management as a distinct discipline and referred to it as "current records." The rapid growth of records management principles in the 1950–1980 period brought about a

change in attitude as is evident in 1984 revision of the ICA's "Dictionary of Archival Terminology." It stated:

This Lexicon was the first attempt on an international scale to draw up a glossary of the main terms then current in archival usage principally in European countries. It was produced in a period of change in the archival world when microforms were in their infancy, when records management was not yet an inseparable component of the archivist's task, and when the application of the computer to the archivist's stock in trade and to his techniques and practices rarely thought of. Now, twenty years on, the archivist's task, his holdings, techniques and practices – and his terminology – have all passed beyond the classical frontiers of his immediate predecessors.

This recognition of the unique principles and practices of records management by archivists has brought about a closer working relationship between the archivists and records managers. Many organization archivists, primarily in the government sector, have expanded their operations to include records management personnel while others coordinate the overall records needs of the organization with separate records management departments. Records management departments, in the private sector, have generally included the identification and collection of historical (archival) records. It has also brought about a cooperative effort in conferences and technical studies between the associations representing the two professions.

In 1969 individual records management group activities were conducted primarily in Melbourne (Victoria) and Sydney (New South Wales) in Australia. This, in turn, led to State Associations being formed in those two states. The pilot committee formed to consider formation of a Federal association, were assisted by a group from the ARMA organization (Eunice Thompson, O. Crawford Jenkins, William P. Southard, John D. Culton, and William Benedon). The ARMA "Records Management Workshop" and the records management objectives it addressed were used in forming the objectives for an association. The Records Management Association of Australia (RMAA) was formed later that year. With the addition of a chapter in New Zealand, the name Australia was changed to Australasia. It currently has nine branches throughout Australasia.

In 1970, Tom Lovett, an RMAA past president, recommended the formation of the International Records Management Council (IRMC) for the worldwide exchange of information and publication on records management. It included, in addition to ARMA and RMAA, the Records Management Society of Great Britain, the Records Management Association of the Philippines, the Records Management Association of South Africa, as well as individual memberships worldwide. It was funded by the individual organizations and published a multilingual *International Records Management Journal* as well as special records management studies and multilingual glossaries (French, German, Japanese, and Portuguese). As the

individual country records management associations started to acquire international memberships, support for the IRMC was not provided and it is currently dormant. It currently has a chapter in Japan and individual memberships in 30 countries around the world and maintains an ongoing working relationship with ICA through joint committees, seminars, and publications.

INTERNATIONAL STANDARD

Standards are a part of a profession's efforts to define and promote the "best practices" to be followed in organizing and using any given technology or process. Standards are developed through a sequence of submittals, reviews, and approvals. Organizations have been established in every country to develop standards and in this process to set development procedures, coordinate participation with professional organizations, and to publish approved standards. In the United States it is the American National Standards Institute (ANSI). The major international organization is the International Organization for Standards (ISO), founded in 1947 and located in Geneva, Switzerland.

Most of the international standards relative to records management have been in the area of technologies, such as micrographics and computerized applications. American professional groups have participated in these efforts, mainly AIIM. Individual records management associations have issued individual country approved standards. The first international standard to focus on records management principles was ISO 9000. The global recognition of this standard for measuring product quality in international trade resulted in a coordinated effort for compliance. It brought with it the need for high-level and organization-wide attention to managing quality records. Although the term "records management" is not used directly in the standard, the control element it addresses are clearly founded on records management principles.

The most significant standard, to date, in the history of the development of records management was the issuance of an international standard (ISO15489) in 2001. It addressed all of the principles outlined in the introduction to this entry and set forth guidelines needed for their proper implementation. It provided the needed policy and management involvement and direction for its success. The development of the standard came about through the efforts of the Records Management Association of Australasia. In 1996, as a result of a cooperative effort in Australia between government and public interests, the Australian Records and Information Standard (AS4390) was issued. The positive response from records organizations worldwide led to a concerted effort for an international standard and ISO15489 was the result. The

Association of Records Managers and Administrators (ARMA) held a special program at its Montreal conference in 2001 to launch the standard. It included a Web broadcast to records managers gathered in England for a conference of the Public Records Office.

The NARA, like other government archival organizations worldwide has developed and issued standards that are primarily applicable to government agencies. (<http://www.archives.gov>) They cover all the standard elements of a records management program. These have been adaptable to business as well. In keeping with the concept of addressing all media, the agency in 1997 adopted the Department of Defense (DOD5025.2) design criteria standards for electronic records management applications. Vendors providing such software to Federal government agencies must abide by this standard.

ARMA, International, through its Standards Development Committee has also issued standards on various aspects of records management that have become approved U.S. standards.

CONCLUSION

The history of RIM has been an uphill struggle to convince management that it was not a file and find occupation but a discipline that, properly applied, could assure the effective and economical use of an important business asset. It elevated an "out of sight, out of mind" approach to inactive records, evidenced by records stored in capitol building domes, basements, attics, moth-balled navy ships, to modern low-cost records center. It assured the orderly and timely disposition of unneeded records. It provided timely access to both active and inactive records needed to conduct daily business and support litigation. Business continuity and the information needed to resume or continue business following a disaster has become a clearly defined program and "vital records" are clearly identified and protected. Records and information management has become an essential ally in the development of systems, the selection of equipment, and the utilization of technologies.

Legislation has also had a major impact on the acceptance and growth of records management. Laws are being continually enacted that address the requirements for proper documentation for business actions and transactions. The Federal Register, issued daily by the NARA, is an ongoing record of rules and procedures that are published for public comment or have been adopted. Records accessibility and access were prominent issues with the passages of the Freedom of Information Act in 1966 and the Privacy Act of 1974. The Paperwork Reduction Act of 1980 addressed efforts to reduce the amount and cost of submitting government reports by requiring agency justification of need and reporting effort. The Occupational Safety and Health Act

(OSHA) and the Employee Retirement Income Security Act (ERISA) impacted the demands for retaining employee records. Health Insurance Portability and Accountability Act (HIPAA) in 2001 established national standards for protecting individual medical records and personal health information. The most significant legislation to date, impacting on the need for and importance of a sound records management program, has been the Sarbanes–Oxley Act of 2002.

The Sarbanes–Oxley Act was a legislative reaction to a series of major corporate accounting scandals involving such companies as WorldCom, Tyco International, and Enron. These scandals, involving corporate executive and leading accounting firms, resulted in investor losses of billions of dollars from share losses. The act mandated new and enhanced standards for all United States public company boards, management, and public accounting firms, including the retention and filing requirements of filing and auditing records.

All regulations regarding the availability and retention of records are applicable regardless of the format in which they are produced. In many cases it is specified that the evidence copy must be produced in paper regardless of the media employed in its generation. The extensive use of electronically stored information today has resulted in changes to the Federal Rules of Civil Procedure (FRCP). Electronic discovery has become a critical factor in litigation and these rules address the requirements for the maintenance and production of records on such media. In 2004, The Sedona Conference addressed the critical issue anti-trust law, complex litigation, and intellectual property in the *Sedona Guidelines: Best Practices and Commentary for Managing Information and Records in the Electronic Age* (http://www.thesedonaconference.org/contact_html).

Information management is the process of identifying and utilizing all the information disciplines and information resources organization-wide to achieve efficient, effective, and competitive management decisions. An organization can best achieve this goal by implementing a workable system that manages the creation, processing, use, maintenance, protection, and disposition of records, regardless of media. It is, therefore, essential that such a system involves all the disciplines that contribute to the maximum utilization and management of information. This interdisciplinary approach includes records management, computer systems, telecommunications, library sciences, archives management, and general management. This entry has addressed the history and maturing value of records management as part of this “interdisciplinary approach.”

History of the Book

Jonathan Rose

Department of History, Drew University, Madison, New Jersey, U.S.A.

Abstract

The history of the book is a new academic field that explores how books shape society and how society shapes books. It covers not only books per se but all kinds of documents, including manuscripts, periodicals, newspapers, and ephemera. It addresses the social, economic, and cultural history of authorship, editing, scribal and print production, publishing, bookselling, literary property, libraries, censorship, literary criticism, literacy, and reading.

Editor's note: Other scholars sometimes use the term “the new book history” to distinguish this emerging multidisciplinary field from those earlier studies that focused mainly on the physical book and the changes it underwent over time. For coverage of earlier bibliographic and historical studies that focus on books and printers see the following entries in this encyclopedia: “Bibliographical Society of America (BSA),” p. 517; “Bibliographical Society [London],” p. 510; “Bibliography,” p. 522; “History of Paper,” p. 2107; “History of Three Basic Printing Processes,” p. 2148; “Illumination [ELIS Classic],” p. 2233; “Incunabula [ELIS Classic],” p. 2254; “Papyrology,” p. 4106; “Private Presses and Fine Printing [ELIS Classic],” p. 4297; and “Provenance of Rare Books,” p. 4333.

One of the newest fields of academic research—and one of obvious interest to librarians—is the history of the book. Its basic premise is simple: that books shape society, and society shapes books. In the original Anglo-Saxon, *bok* could mean any kind of document, and book historians likewise define the term expansively, to include not only books per se but also manuscripts, periodicals, newspapers, and ephemera. Some scholars prefer the term “print culture history,” though that has the disadvantage of excluding written documents. But all book historians agree that, in all literate cultures, script and print are the prime means of communicating information, disseminating ideas, preserving memory, distributing wealth, and exercising power. (This is not to deny the importance of oral and electronic media, but they pose different historiographical questions and involve different methodologies and sources.) Book historians are concerned with the creation, dissemination, uses, storage, and destruction of documents: thus they focus on the social, economic, and cultural history of authorship, editing, scribal and print production, publishing, bookselling, literary property, libraries, censorship, literary criticism, literacy, and reading.

Histories of books and printing go back almost as far as the printing press itself, but only more recently have historians systematically studied books to illuminate larger movements in society. Daniel Mornet's 1910 essay “Les Enseignements des bibliothèques privées” searched 500 prerevolutionary French private libraries and found only one copy of the book that was supposed to have sparked the revolution, Jean-Jacques Rousseau's *The Social Contract*. In *The Puritan Pronaos* (1936), Samuel Eliot Morison recognized that the intellectual climate of seventeenth-century New England could not be understood apart from its printers, booksellers, and libraries. Richard D. Altick's *The English Common Reader 1800–1900* (1957) explored several dimensions of book history avant la lettre: literacy education, public libraries, readers, the book trade, periodicals, and newspapers. In *L'Apparition du livre* (1958) (translated as *The Coming of the Book: The Impact of Printing 1450–1800*), Lucien Febvre and Henri-Jean Martin deployed the methods of the *Annales* school of history to explain the role of print technology in the development of capitalism and Protestantism. In 1979 two major books introduced American historians to the history of the book and popularized the term (from the French *l'histoire du livre*): Elizabeth Eisenstein's *The Printing Press as an Agent of Change* and Robert Darnton's *The Business of Enlightenment: A Publishing History of the Encyclopédie, 1775–1800*. The book was coming to be seen more and more as a driving force in history, a factor that could help explain the dissemination of the Renaissance, the Protestant Reformation, the rise of modern science, and the French Revolution.

In the final years of the twentieth century, book history began to create the structures of an organized academic discipline. The first specialists in the field had to train themselves, until formal graduate programs were set up at the University of Toronto, the University of Wisconsin, the University of Iowa, Florida State University, Drew University, the University of London, the University of Edinburgh, Leiden University, and the Johannes

Gutenberg University in Mainz. The first volume of the *Annual Bibliography of the History of the Printed Book and Libraries* was published in 1970: the information therein is now being transferred to *Book History Online*, based at the Koninklijke Bibliotheek (the National Library of the Netherlands). The Society for the History of Authorship, Reading and Publishing (SHARP) was founded in 1991 and held its first annual conference at the CUNY Graduate Center in 1993. It became the leading international organization of book historians, at least in the Anglophone world. Its Web site, at <http://www.sharpweb.org>, is the most current and extensive listing of resources in the field, with links to publishers' archives, book catalogs, scholarly journals, databases, ephemera collections, research projects, museums, libraries, online exhibits, course syllabi, academic programs, and conferences. In addition to SHARP there arose more specialized scholarly societies defined by nationality or subfields, such as the Book Trade History Group (Britain), the Canadian Association for the Study of Book Culture, the Nederlandse Boekhistorische Vereniging (Netherlands), the Gesellschaft für Buchforschung in Österreich (Austria), the Early Book Society, and the Textbook Colloquium. New journals appeared, such as *Publishing History* (Britain), *Book History* (United States), and the *Jaarboek Nederlandse Boekgeschiedenis* (Netherlands). Textbooks were produced, and monograph series were launched by a growing number of university presses (e.g., Penn State, University of Massachusetts, University of Toronto). Ultimately, all this research was distilled into encyclopedic multivolume histories of the book in the United States, Britain, Scotland, France, Australia, and Canada.

Book history became a highly interdisciplinary discipline, bringing together scholars from a wide range of fields. Sociologists, anthropologists, and reading instructors found it a useful method for studying the uses of literacy. Art historians came to appreciate that the physical book was itself an important art form. Students of theology increasingly understood that books are a prime means of spreading gospels, and that every religious denomination is also a publishing house. (The techniques of mass-market publishing were pioneered by evangelical Christians in early nineteenth-century Britain and America.) And publishing professionals began to take an interest in the history of their business. But most book historians are historians, literary scholars, or librarians—and all three had compelling reasons to be attracted to this new academic enterprise.

By the 1970s intellectual historians found themselves challenged by social historians, who often dismissed the history of ideas as “elitist,” oblivious to economic realities and material culture. In fact the project of intellectual history could no longer limit itself to describing conversations among great thinkers: it had to explore how ideas were incarnated in published texts and disseminated to

mass audiences. Thus intellectual historians like Robert Darnton met the criticisms of social and economic historians by adopting their methods, studying the *Encyclopédie* as a business venture and tracing the spread of the “low Enlightenment” among common readers. Indeed, book historians reminded social historians of a fact they usually overlooked: that books and the ideas they contain have long been an important part of the everyday lives of ordinary people.

Meanwhile, departments of English and foreign languages were confronted by the rise of postmodern literary theory, which was raising provocative questions about canon formation, reader response, the politics of literary criticism, and the sociology of authorship. These questions needed to be asked, but some Modern Language Association members felt that the answers offered by postmodernists were glib, tendentious, and founded on precious little research. Was the canon simply something constructed by white male critics? Did metropolitan publishers dump European literature on colonized peoples? Do women really read differently from men, and if so, in what ways? (The school of “reader-response critics” was notorious for failing to study actual readers.) “Empirical” was the foulest epithet in the postmodern vocabulary, but some literary scholars began to do the kind of archival research that historians had always done, and their work helped to usher in a “posttheory” revisionist approach to literary history.

Librarians had always felt undervalued in the academic hierarchy, and they were eager to prove that they were more than just warehousekeepers of books. Some of them saw an opportunity in the theories of Michel Foucault, who argued that cultures are defined by how they archive and classify knowledge. In that case, the acquisition, cataloging, borrowing, and culling of books all became vitally important intellectual questions—and librarians, who knew how to find the relevant facts and figures, could make a valuable contribution to writing cultural history.

Regardless of which department they teach in, book historians address the following common questions:

Authorship. Each and every book must be created by someone—or something—but the precise role of the person named on the title page is open to debate. Some literary scholars have gone so far as to proclaim “the death of the author,” arguing that books are called into existence by impersonal social, economic, political, and cultural forces, but this is an extreme position. Most of us would agree that, whoever else was involved in creating *The Pickwick Papers*, Charles Dickens had something to do with it. But book historians rightly insist that no book is created *solely* by its author: publishers, printers, illustrators, designers, binders, salesmen, and lawyers all shape the final product in important ways. And all texts are revised, often dramatically, by editors, as A. Scott Berg illustrated in *Max Perkins: Editor of Genius* (1978). Mary Ann Gillies, in *The Professional Literary Agent in Britain*,

1870–1920 (2007), has focused attention on the most under-researched figure in the book trade, who has played a critical editorial role in advising authors to tailor their manuscripts to the demands of publishers and reading publics. Book history is deeply concerned with the sociology of authorship and has generated quite a large body of literature exploring the gender factor: for example, Susan Coultrap-McQuin's *Doing Literary Business: American Women Writers in the Nineteenth Century* (1990), Bette London's *Writing Double: Women's Literary Partnerships* (1999), and Carla Hesse's *The Other Enlightenment: How French Women Became Modern* (2001). Less attention has been paid to class issues, but see Nigel Cross's *The Common Writer: Life in Nineteenth-Century Grub Street* (1985) and Christopher Hilliard's *To Exercise Our Talents: The Democratization of Writing in Britain* (2006).

Printing. The recent volume *Agent of Change: Print Culture Studies after Elizabeth L. Eisenstein*, edited by Sabrina Alcorn Baron, Eric N. Lindquist, and Eleanor F. Shevlin (2007), is only one manifestation of the wide-ranging scholarly debates that her work incited. Did Gutenberg foment a “print revolution,” or was his impact on European society less dramatic? Did printing make possible certain kinds of books (such as scientific texts) which were not really possible before? Did it promote “fixity of text” or simply perpetuate textual errors (a question explored in Adrian Johns's *The Nature of the Book* [1998])? Why were certain parts of the world (notably India and the Islamic regions) slow to adopt print technology, and what were the social consequences of that delay? How did the adoption of Western print technology in the nineteenth century transform East and South Asia? As the first mass-production industry, was printing the driving force behind the development of modern capitalism? How did printers change literary texts, with or without the permission of the authors (an issue addressed in Allan C. Dooley's *Author and Printer in Victorian England* [1992])? Print technology changed little between 1450 and 1800, but in the nineteenth century there was arguably a second printing revolution, with the introduction of steam power, rotary presses, stereotype plates, and papermaking machines, all of which made possible mass-market publishing. Book historians also explore reproduction technologies other than movable type, both pre-Gutenberg (xylography) and post-Gutenberg (lithography, mimeographing, microfilm, photocopying, desktop publishing, and the e-book).

Publishing. Publishers have long written or commissioned celebratory “house histories,” but book historians have developed this genre to show how particular firms promoted particular kinds of literature—either Tory (David Finkelstein, *The House of Blackwood: Author–Publisher Relations in the Victorian Era* [2002]) or leftist (Sheila Hodges, *Gollancz: The Story of a Publishing House, 1928–1978* [1978]), classics (Jay Satterfield, *The World's Best Books: Taste, Culture, and the Modern*

Library [2002]) or smut (Iain McCalman, *Radical Underworld: Prophets, Revolutionaries and Pornographers in London 1790–1840* [1988]), fine printing (William S. Peterson, *The Kelmscott Press* [1989]) or paperbacks (Thomas L. Bonn, *Heavy Traffic and High Culture: New American Library as Literary Gatekeeper in the Paperback Revolution* [1989]), highbrow (J. H. Willis, Jr., *Leonard and Virginia Woolf as Publishers: The Hogarth Press 1917–41* [1992]), lowbrow (Larry E. Sullivan and Lydia Cushman Schurman, eds., *Pioneers, Passionate Ladies, and Private Eyes: Dime Novels, Series Books, and Paperbacks* [1996]), or somewhere in between (Joan Shelley Rubin, *The Making of Middlebrow Culture* [1992]).

Publishing histories have cast a new light on the work of much-studied authors: see Morton Cohen and Anita Gandolfo, *Lewis Carroll and the House of Macmillan* (1987); Robert L. Patten, *Charles Dickens and His Publishers* (1978); and Peter Shillingsburg, *Pegasus in Harness: Victorian Publishing and W. M. Thackeray* (1992). The very structure of many Victorian novels was determined by their initial publication in serial form, as illuminated by Linda K. Hughes and Michael Lund, *The Victorian Serial* (1991), and Carol A. Martin, *George Eliot's Serial Fiction* (1994).

In one area in particular, book historians have dramatically revised the conventional narrative of literary history. Modernist authors were once accepted at face value as pure artists resisting the commercial pressures imposed by mercenary publishers. But the close study of publishers' ledgers and correspondence reveals a more mixed reality: it turns out that Joseph Conrad, James Joyce, and D. H. Lawrence were interested in profit maximization as well. Some of the key works on “marketing modernism” include James Nelson, *Elkin Mathews: Publisher to Yeats, Joyce, Pound* (1989); Joyce Piell Wexler, *Who Paid for Modernism? Art, Money, and the Fiction of Conrad, Joyce, and Lawrence* (1997); Peter D. McDonald, *British Literary Culture and Publishing Practice 1880–1914* (1997); Lawrence Rainey, *Institutions of Modernism: Literary Elites and Public Culture* (1998); Josephine M. Guy and Ian Small, *Oscar Wilde's Profession: Writing and the Culture Industry in the Late Nineteenth Century* (2000); Paul Delany, *Literature, Money and the Market: From Trollope to Amis* (2002); Catherine Turner, *Marketing Modernism between the Two World Wars* (2003); and Robert W. Trogon, *The Lousy Racket: Hemingway, Scribners, and the Business of Literature* (2007).

Bookselling. Bookseller's records can tell us a great deal about the availability and demand for books in a particular time and place. William J. Gilmore used such sources to illuminate literary life in a backwater of the early American republic, in *Reading Becomes a Necessity of Life: Material and Cultural Life in Rural New England, 1780–1835* (1989). Colporteurs (traveling book peddlers) can sometimes convey a very clear picture of what their customers wanted. And so do histories of big modern

bookselling chains, such as Charles Wilson's *First with the News: The History of W. H. Smith* (1986).

Literary property. The first modern copyright legislation was enacted in Great Britain in 1710, and its impact is described in Mark Rose's *Authors and Owners: The Invention of Copyright* (1993). However, the concept of literary property is almost as old as printing itself, as explained in Cynthia J. Brown's *Poets, Patrons, and Printers: Crisis of Authority in Late Medieval France* (1995) and Joseph Loewenstein's *The Author's Due: Printing and the Prehistory of Copyright* (2002). Until Congress ratified an international copyright treaty in 1891, American readers enjoyed a windfall of cheap pirated foreign literature, as analyzed most recently in Meredith L. McGill's *American Literature and the Culture of Reprinting, 1834–1853* (2003). And Chinese literature has been profoundly shaped by a traditional lack of respect for literary property: see William P. Alford's *To Steal a Book is an Elegant Offense: Intellectual Property Law in Chinese Civilization* (1995) and Andrew C. Mertha's *The Politics of Piracy: Intellectual Property in Contemporary China* (2005).

Libraries. Library history was once a relentlessly uplifting tale about public enlightenment, philanthropic gentlemen, and dedicated collection-builders. Under the influence of book history, however, this field has become more deeply rooted in social history, as exemplified in Alistair Black's *A New History of the English Public Library: Social and Intellectual Contexts, 1850–1914* (1996). In *Reading on the Middle Border: The Culture of Print in Late Nineteenth-Century Osage, Iowa* (2001), Christine Pawley analyzed library records to reconstruct the intellectual milieu of an entire midwestern community. And in *Free to All: Carnegie Libraries and American Culture, 1890–1920* (1995), Abigail Van Slyck used the public library movement as a window into the history of American philanthropy and civic architecture. Wayne Wiegand's *Irrepressible Reformer* (1996) was more than just a biography of Melvil Dewey: it cast light on the invention of information science and the ideological biases built into that profession. One of the distinguishing features of this new approach to library history is a willingness to explore some of its grimmer aspects: for example the McCarthy era, in Louise S. Robbins, *The Dismissal of Miss Ruth Brown: Civil Rights, Censorship, and the American Library* (2000); or convict libraries, in Janet Fyfe, *Books Behind Bars: The Role of Books, Reading, and Libraries in British Prison Reform, 1701–1911* (1992); or James Raven, ed., *Lost Libraries: The Destruction of Great Book Collections since Antiquity* (2004); or, darker still, Ambrus Miskolczy's *Hitler's Library: A Socio-Historical Overview* (2003) and Timothy Ryback's *Hitler's Private Library: The Books That Shaped His Life* (2008). In 12 years the Nazis destroyed an estimated 100 million volumes throughout Europe, as documented in David Shavit, *Hunger for the Printed Word: Books and*

Libraries in the Jewish Ghettos of Nazi-Occupied Europe (1997); and Jonathan Rose, ed., *The Holocaust and the Book: Destruction and Preservation* (2001). See also Rebecca Knuth's *Libricide: The Regime-Sponsored Destruction of Books and Libraries in the Twentieth Century* (2003).

Censorship. It is bleakly ironic that the twentieth century, when most Western societies achieved near-universal literacy, also witnessed the most ruthless and extreme suppression of literature. But censorship and expurgation—for moral, political, or religious reasons—have always been with us. Book historians have set themselves the task of explaining why, how, and upon whom censorship was imposed. For example, in *Word Crimes: Blasphemy, Culture, and Literature in Nineteenth-Century England* (1998), Joss Marsh found that blasphemy laws were enforced only against working-class atheists, not gentleman agnostics like T. H. Huxley. Scholars have found that censorship in ancien régime France and Czarist Russia was notoriously leaky and inefficient, allowing in much subversive literature. And we have already begun to study the newest front in the censorship wars: see *The Rushdie File*, ed. Lisa Appignanesi and Sara Maitland (1990). Book historians have also pioneered the serious scholarly study of pornography and its role in culture and politics: see Lynn Hunt, ed., *The Invention of Pornography: Obscenity and the Origins of Modernity, 1500–1800* (1993), and Robert Darnton, *The Forbidden Best-Sellers of Pre-Revolutionary France* (1995).

Literacy and Reading. Where earlier historians focused on estimating rates of literacy, book historians such as David Vincent (*Literacy and Popular Culture: England 1750–1914* [1989]) have delineated the everyday uses of literacy—in the workplace, in political and labor organizations, in everyday letter-writing. A fairly high degree of literacy was necessary to negotiate modern urban environments, as illustrated by Peter Fritzsche in *Reading Berlin 1900* (1996) and David M. Henkin in *City Reading: Written Words and Public Spaces in Antebellum New York* (1998).

Until fairly recently it was widely assumed that recovering the intellectual experiences of ordinary readers in history was impossible, but a growing number of book historians have managed to penetrate that mystery. They have used such sources as probate and booksellers' records, which reveal the ownership and distribution of books. Remarkably detailed sociological surveys of reading were conducted as far back as the 1790s (in the case of *The Statistical Account of Scotland*) and in the old USSR (used by Stephen Lovell to write *The Russian Reading Revolution: Print Culture in the Soviet and Post-Soviet Eras* [2000]). The minutes of reading groups and literary societies can be mined for what they reveal about popular reading habits, as Elizabeth McHenry did in *Forgotten Readers: Recovering the Lost History of African–American Literary Societies* (2002). Equally illuminating

are library borrowing records and the memoirs of plebeian readers, as employed in Jonathan Rose's *The Intellectual Life of the British Working Classes* (2001). Much information about learning literacy can be found in the records of educational institutions: Heather Andrea Williams made use of the Freedmen's Bureau archives in *Self-Taught: African American Education in Slavery and Freedom* (2005). No less valuable are letters to magazine and newspaper editors, particularly those that were never published, as studied by David Nord in *Communities of Journalism: A History of American Newspapers and Their Readers* (2001). In his *Faith in Reading: Religious Publishing and the Birth of Mass Media in America* (2004), Nord also made effective use of reports that canvassers sent back to evangelical publishers, essentially an early form of market research. For their book *Everyday Ideas: Socioliterary Experience among Antebellum New Englanders* (2006), Ronald J. Zboray and Mary Saracino Zboray gleaned observations about reading from the letters and diaries of more than 900 individuals. Other revealing sources include interviews (Martyn Lyons and Lucy Taska, *Australian Readers Remember: An Oral History of Reading 1890–1930* [1992]), fan mail (Clarence Karr, *Authors and Audiences: Popular Canadian Fiction in the Early Twentieth Century* [2000]), iconography in illuminated manuscripts (Laurel Amtower, *Engaging Words: The Culture of Reading in the Later Middle Ages* [2000]), and comments scribbled in margins (Heather Jackson, *Marginalia: Readers Writing in Books* [2001]). As Carlo Ginzburg demonstrated in *The Cheese and the Worms* (1980), the Inquisition was keenly interested in what people were reading, and their proceedings are an invaluable historical resource.

Finally, the Reading Experience Database, begun in 1996, is assembling a searchable pool of thousands of individual reading experiences in Britain between 1450 and 1945 (<http://www.open.ac.uk/Arts/RED/>). And in the United States, the "What Middletown Read" project has constructed a searchable database of the usage of the Muncie Public Library between 1891 and 1902, covering more than 6,000 borrowers, 13,000 volumes, and 400,000 loans (<http://www.bsu.edu/middletown/wmr/>).

Literary politics. Canon formation has been a hotly contested and highly politicized issue among the last generation of literary scholars. A number of book historians have addressed it in a systematic way, notably Jan Gorak in *The Making of the Modern Canon* (1991), John Guillory in *Cultural Capital: The Problem of Literary Canon Formation* (1993), and Timothy Morris in *Becoming Canonical in American Poetry* (1995). Sex bias in literary criticism, no less controversial a topic, is treated in Nicola Thompson's *Reviewing Sex: Gender and the Reception of Victorian Novels* (1996). For studies of single authors, a model is John Rodden's *The Politics of Literary Reputation* (2nd ed., 2002), which retells the intellectual history of the Cold War though a survey of critical responses to

George Orwell. The question of what gets translated—and how—can also be political, as André Lefevere has explained in *Translation, Rewriting, and the Manipulation of Literary Fame* (1992). Specialized studies in this field have often focused on Germany: Walter Grünzweig, *Constructing the German Walt Whitman* (1995); Bernhard Fabian, *The English Book in Eighteenth-Century Germany* (1992); and Fania Oz-Salzberger, *Translating the Enlightenment: Scottish Civic Discourse in Eighteenth-Century Germany* (1995).

Studies of the development of English as a scholarly discipline, in both the United States and Britain, inevitably focus on academic politics: Chris Baldick's *The Social Mission of English Criticism 1848–1932* (1983) (a Marxist perspective), Franklin Court's *Institutionalizing English Literature* (1992), John Dixon's *A Schooling in "English"* (1991) (more sympathetic than either Baldick or Court), David R. Shumway's *Creating American Civilization: A Genealogy of American Literature as an Academic Discipline* (1994), Kermit Vanderbilt's *American Literature and the Academy* (1986), and Gerald Graff's *Professing Literature: A Institutional History* (2nd ed., 2007). For a devastating treatment of postmodern criticism, see David Lehman, *Signs of the Times: Deconstruction and the Fall of Paul de Man* (1991).

There have also been numerous studies of the political impact of books, including two on *Silent Spring*: Priscilla Coit Murphy's *What a Book Can Do: The Publication and Reception of Silent Spring* (2005) and Mark Hamilton Lytle's *The Gentle Subversive: Rachel Carson, Silent Spring, and the Rise of the Environmental Movement* (2007). Following the lead of Robert Darnton, several historians have looked for the seeds of the French Revolution in print culture: Jack R. Censer in *The French Press in the Age of Enlightenment* (1994), Roger Chartier in *The Cultural Origins of the French Revolution* (1991), Elizabeth Eisenstein in *Grub Street Abroad: Aspects of the French Cosmopolitan Press from the Age of Louis XIV to the French Revolution* (1992), Arlette Farge in *Subversive Words: Public Opinion in Eighteenth-Century France* (1994), Dena Goodman in *The Republic of Letters: A Cultural History of the French Enlightenment* (1994), and Jeremy Popkin in *News and Politics in the Age of Revolution: Jean Luzac's Gazette de Leyde* (1989). An entire volume of critical essays has been devoted to *The Darnton Debate: Books and Revolution in the Eighteenth Century* (ed. Haydn T. Mason, 1998).

Science. Elizabeth Eisenstein argued that print made the scientific revolution possible, and in her wake historians have investigated the publication and reception of scientific ideas. Here the outstanding work is James Secord, *Victorian Sensation: The Extraordinary Publication, Reception, and Secret Authorship of Vestiges of the Natural History of Creation* (2000). But see as well Aileen Fyfe, *Science and Salvation: Evangelical Popular Science Publishing in Victorian Britain* (2004); Lydia Marinelli

and Andreas Mayer, *Dreaming by the Book: Freud's Interpretation of Dreams and the History of the Psychoanalytic Movement* (2003); and Marina Frasca-Spada and Nick Jardine, eds., *Books and the Sciences in History* (2000).

Lexicography. Print technology made the national standardization of spelling and vocabulary necessary, and that gave rise to the modern dictionary, which in turn has been an almost irresistible force for defining language. Critics from various points on the ideological compass have charged lexicographers with the crimes of slanginess, "prescriptivism," or linguistic imperialism. Book historians, however, recognize that dictionary makers are publishing professionals who have to balance a host of completing pressures: they must work within deadlines and budgets and space limits, they must coordinate the work of an army of contributors and subeditors, they must track down and historicize and define literally hundreds of thousands of words, and they must produce a book that is both marketable and absolutely accurate. Studies that are particularly sensitive to these problems include Herbert C. Morton's *The Story of Webster's Third: Philip Gove's Controversial Dictionary and Its Critics* (1994), Allen Reddick's *The Making of Johnson's Dictionary, 1746–1773* (2nd ed., 1996), and Lynda Mugglestone's *Lost for Words: The Hidden History of the Oxford English Dictionary* (2005).

Future directions. Until very recently book history was a First World enterprise, concentrating almost exclusively on Europe, North America, and Australasia, but now it is beginning to engage other parts of the globe as well. India in particular has attracted a critical mass of scholars, among them Priya Joshi (*In Another Country: Colonialism, Culture and the English Novel in India* [2002]), Anindita Ghosh (*Power in Print: Popular Publishing and the Politics of Language and Culture in a Colonial Society, 1778–1905* [2006]), and Rimi Chatterjee (*Empires of the Mind: A History of Oxford University Press in India under the Raj* [2006]). Recovering the African common reader might seem to be an impossible task, but it has been accomplished by Wendy Griswold (*Bearing Witness: Readers, Writers and the Novel in Nigeria* [2000]) and Stephanie Newell (*Literary Culture in Colonial Ghana: How to Play the Game of Life* [2002]). For other groundbreaking works, see Christopher A. Reed's *Gutenberg in Shanghai: Chinese Print Capitalism, 1876–1937* (2004)

and Eugenia Roldán Vera's *The British Book Trade and Spanish American Independence: Education and Knowledge Transmission in Transcontinental Perspective* (2003).

As noted at the outset, book history is concerned with all types of documents, so the next logical frontier for the field should be the history of archives. Our culture is defined by the records that we choose to preserve or destroy, their organization and accessibility, and the information they contain, all of which determines the kinds of history we can reconstruct. The importance of this type of scholarship for all historians should be obvious, but archival history is still a very new field, so new that it is scarcely organized. It has no dedicated academic journals or societies, though the International Conference on the History of Records and Archives (I-CHORA) has been meeting since 2003. For examples of some recent work, see *Ancient Archives and Archival Traditions: Concepts of Record-Keeping in the Ancient World*, ed. Maria Brosius (2003). A promising approach to this subject is via the historiography of paperwork, for example Miles Ogborn's *Indian Ink: Script and Print in the Making of the English East India Company* (2007), Cornelia Vismann's *Files: Law and Media Technology* (abridged and translated by Geoffrey Winthrop-Young, 2008), and Jacob Soll's forthcoming *The Information Master: Jean-Baptiste Colbert's Secret State Intelligence System*.

History: Three Basic Printing Processes

Sidney E. Berger

Phillips Library, Peabody Essex Museum, Salem, Massachusetts, U.S.A.

Abstract

The present entry will discuss three types of printing processes as they have been practiced in the West for centuries. Moveable type printing that originated with Johannes Gutenberg in Europe is called relief printing because the ink adheres to a raised surface from which it is imparted to the printed surface. The second basic kind of printing in the hand press period is intaglio, that is, printing from inks delivered to a surface from beneath the surface of the printing block. The third type of printing is called planographic and the process is referred to as lithography, which involves printing from the flat surface of a stone.

INTRODUCTION

Printing was developed in China long before Johannes Gutenberg came on the scene. The Chinese were printing from clay maybe by the eighth century and certainly by the ninth century. Also by the ninth century they were printing from wood blocks, carved (in reverse, i.e., in mirror writing) from a flat surface. Hence, the first printing that we know of is one of three types of printing: relief, intaglio, and planographic. The present entry will discuss these three types of printing as they have been practiced in the West for centuries.

RELIEF PRINTING

When something is in relief, it is raised up from a surface below. A relief map shows mountains that actually protrude upward from the surface of the map.

With the growth of the guild system in the Middle Ages, there was a concomitant growth of the middle class, with a simultaneous enlargement of the educational system. With the flow of money to the middle class, there was an increase in leisure time and a parallel demand for education. The number of books produced in the monasteries and by the Stationers—by secular scribes—could not keep up with the demand caused by the expansion of the education system. Manuscript books could be produced only one at a time. But the numbers of students were increasing rapidly.

In this climate, the need arose for a process of book production that would allow multiple copies of books, rather than one at a time. Johannes Gutenberg (1398–February 3, 1468) satisfied this need by adapting several techniques of metallurgy and design to a new craft: printing.

Gutenberg neither invented printing nor did he invent the press, which had existed for centuries before him, for pressing olives or grapes. He did not invent ink, which, of course, had existed for centuries and was used in the

production of manuscripts. His genius lay in the use he made of his metal-casting skills, combined with a couple of innovations that made relief printing as we know it possible.

The Chinese could cast words in matrixes (also called matrices), but because they had a pictographic language, every word had to be cast separately. A text with, say, 5000 different words would have required that many individual matrixes. Gutenberg had the good fortune to live in an area of the world that used not pictograms but the individual letters of an alphabet to build up words. The number of matrixes he needed to create was only a tiny fraction of the number needed for a pictographic language.

Gutenberg's first challenge was to design a full font—an alphabet and all the other characters he would need: letters of various sizes, numbers, punctuation signs, and other special figures. With manuscript hands as his model, he designed a font of printing type that perfectly suited his needs, looking sufficiently like the perfectly legible handwriting of scribes.

In fact, though he was creating printed books, to an observer not familiar with printing (and practically no one was since these were the first printed items in the West), what he made looked like multiple, identical copies of manuscripts. Items that were absolutely identical might have received the censure of the Church as being produced with the help of the Devil. Gutenberg got around that potential peril by producing as his first book a Bible.

With a full font designed, Gutenberg set about the kind of work he was familiar with: creating matrixes to cast the type. As a goldsmith, he knew how to create matrixes. He began with a short iron bar, squared off horizontally and vertically. On one end it had a perfectly flat surface onto which he transferred, backward (that is, in mirror writing) the character he wanted to cast. As he carved and filed away, he removed metal from the end of the bar—called a *punch*—leaving behind in relief the character he would eventually cast. As he got closer and closer to the final

form, he would take smoke proofs. That is, he would hold the carved end of the punch in a flame, allowing lamp-black to settle on the punch's surface. Then he would press the punch onto a piece of paper to make a print of the character.

If it was not filed or "carved" sufficiently, he would continue, taking further smoke proofs, until it was just as he wanted it. If he went too far, removing too much metal, he would have to begin again. When the punch was exactly as he wanted it, he would hold it in a flame until it glowed to just the right color, and then he would plunge it into cold water to harden it. The steel punch was now ready for the next step: creating the matrix.

A small squared-off bar of copper was the raw matrix. Gutenberg carefully hammered the punch into the copper, creating in it the impression of the character from the tip of the punch. It displaced some copper, so the matrix had to be filed down and squared off—called "justifying the matrix." The punch had to make an impression in the copper to exactly the right depth (the same depth into every matrix for all of the characters). This would assure that every piece of type—every "sort"—would be exactly the same height from its feet to its face. This of course was necessary since all the sorts, when composed into a text, needed to be exactly the same height from foot to face, creating a smooth surface of faces to receive the ink uniformly and to offer up a perfectly uniform impression to the paper or vellum laid upon it.

Once the matrix was justified, it was ready for casting. Here is where Gutenberg's great genius lay: he created an adjustable mold, adjustable "left to right" to accommodate matrices of different horizontal measures. Thus, a matrix of an "I" would fit into the mold with only a narrow "funnel"—formed by the two halves of the mold—above it; while an "M" would be in a matrix that was considerably wider left to right. The mold could slide open to accommodate the wider letter.

With the matrix at the bottom of the mold, which formed a little funnel above it, the type caster would pour molten type metal down the funnel. The metal, which would solidify in a split second, would fill the impression of the character in the matrix and create the sort, with a "jet" of metal above the just-cast sort. This jet, made up of the extra metal poured in that was not needed to create the sort, would be broken off, the sort would be put with other like sorts, the type would be "brushed off" to remove any extra slag or other minute particles of metal that attached to the sort, and the feet of the sort would be created when the point at which the jet was attached would be filed down—thus creating a tiny groove on the bottom of every piece of type, and two "feet" around the groove that the sort would sit on. (All the broken-off jets would be dropped back into the melting pot to be used for further casting.)

When the requisite number of characters was cast from that matrix, it would be removed from the hand mold and

another matrix, created in the same way the previous one was, would be put in and used for casting.

Once the typesetter had created all the sorts needed and distributed them into a typecase into little compartments, the compositor would take these sorts and place them one at a time into a handheld device called a composing stick, lining up the sorts to form words, sentences, and paragraphs, or whatever the copy required. When the composing stick was full, the lines of type, all justified to exactly the same length in the stick, would be transferred to a galley, a three-sided tray (usually made of metal). More lines of type from the composing stick would join the earlier ones until the text was completed, or until the galley was full. Additional galleys were needed for longer texts, and, in fact, a whole galley rack holding perhaps dozens of galleys could contain the text of an entire book.

The text would be proofed in the galleys (hence our modern term "galley proofs" or "galleys"), corrected, and proofed again. Eventually the printer would transfer from the galley to the bed of the press, the pages she or he needed to print one side of a sheet. Later the sheet would be "perfected"—that is, the second side of the sheet would be printed. Little by little stacks of printed and perfected sheets would form, and when all the sheets were finished being printed, they would be folded and gathered into groups (called "quires," "gatherings," or "signatures") in the proper sequence to form the continuous text from beginning to end. At this point, the printing was done and the sheets went off to the binder.

* * *

In the hand press period (before, say, 1800), printers faced a dilemma: once they set a book into type, how many copies should they print? If they did a run of 1000 copies and sold only half, they would lose money. If they printed 1000 copies and distributed the type back into the typecases, and then needed more copies, they would have to reset the type. Further, if they printed the 1000 but thought they might need to print more, they could store the type in galleys. But this would take up a good deal of space, and it would render the type unusable for other projects.

The solution was stereotyping, which entailed taking a mold of the pages of type—in plaster, clay, or papier-maché—and using that mold to cast a plate that contained a perfect image of the standing type. (Note that the printing from stereotype plates is indistinguishable from the printing of the text from the type itself. They are both relief printing and will leave the same kind of indentation in the paper. Also, since an edition of a text is constituted by all of the copies printed from a single setting of type, pages printed from type and those printed from stereotype plates cast from that same type are both part of the same edition.)

Many experiments in stereotyping as early as the close of the seventeenth century took place, but it was William Ged in Edinburgh who seems to have made the first

practicable stereotype plates about 1725.^[1] (This statement is on p. 526. Though this is an old reference book, it is authoritative and reliable.) The process became commercially accepted with its “reinvention” by Andrew Tilloch,^[2] the editor of the *Philosophical Magazine*. (The Dictionary says, “Tilloch declared. . . that he had known nothing of Ged’s process, but this is not believed by [Luke] Hansard,” the author of a well read printer’s manual (p. 527). Tilloch partnered with Andrew Foulis, printer at the University of Glasgow, in 1782. In 1784 they took out four patents for printing with metal plates rather than from standing type.^[3])

Stereotyping was almost completely superseded by electrotyping, another way to make a matrix for casting printing plates. The set type is placed in a galvanic bath and a perfect mold of another metal, usually copper, is formed over the type. It is considerably more complicated than this brief statement indicates, but the point is that a printing plate that looks like a stereotype plate, but that is covered with a layer of copper, is formed, and books can be printed from the plates. Copper is much more durable than is the type metal used in stereos, which is a composition of about 80% lead, 10% tin, and 10% antimony. Hence, electros will hold up longer than will stereos.

Electrotype plates, like stereotypes, are of the same edition as was the type they were made from, and they print in relief as do the type and the stereos.^[4] (Note that nickel, brass, or steel could be deposited onto the original form of type, but copper was the most common. See the *American Dictionary*, p. 164.) Further, since the printer using these plates is not constrained by thousands of pieces of type, the plates can be bent in such a way as to fit over a cylinder and can be placed into high-speed cylinder presses. Electros can also be made from woodcuts, allowing for the high-speed printing of text and illustration in one operation.

INTAGLIO PRINTING

The second basic kind of printing in the hand press period is intaglio, that is, printing from inks delivered to a surface from beneath the surface of the printing block. (Note that the G in the word “intaglio” is not pronounced.) The text—verbal or pictorial—is incised or carved into the surface of the plate, which traditionally was wood or copper, but later on could be zinc, magnesium, linoleum, or any of several other materials.

Relief printing preceded intaglio by several centuries, probably invented by the Chinese in the second century. “Intaglio engraving, as a method of making prints, was invented in Germany by the 1430s”^[5] and the method was soon employed by the Italians and Dutch, though the incising of surfaces of metals clearly predates this by centuries in the decoration of metal objects like armor or trays.

In the most basic method, the artist, using burins and gravers, would incise the image or text into the plate,

leaving grooves of varying widths and depths, then cover the surface of the plate with ink, which was pressed into the grooves. The surface of the plate would then be wiped clean with a tarlatan, a plain-weaved cotton fabric (sometimes the artist would swipe a bare hand over the plate’s surface for the final wiping), leaving the ink in the grooves.

A sheet of dampened paper is then placed over the plate, backed with a soft blanket, and run through the press under great pressure. The dampened paper is pressed into the grooves and picks up the ink, transferring the image or text to the sheet.

Additionally, before the printing but after the wiping of the plate, the plate could be colored in various ways on its surface, allowing the artist to add a second, third, or many colors to the final print, creating a monoprint—a print unique in that, while the intaglio-printed text can be reproduced, the coloring on the surface of the plate cannot.

What has just been described is one kind of intaglio printing, engraving, since the artist has engraved the surface of the plate with tools. There is another way to get the grooves into the plate: etching. This is done using acids that burn into the surface of the plate. In etching, the plate is covered in wax, which is impervious to acid. The artist, using a fine metal tool like a needle, scratches off the wax where the image is to go, exposing the metal. When acid is put onto the plate (either being washed over the surface or having the plate dipped into the acid bath), the acid etches the plate. The longer the metal is exposed to the acid, the deeper and wider will be the grooves and dots.^[6]

A related method which is not strictly intaglio is drypoint printing. The artist uses the gravers and burins as with engraving, but instead of removing the incised-out metal, the artist leaves a burr of metal at the edges of the incised grooves. These get inked (rather than having the ink go into the grooves) and the print is made from the inked burrs. Since the paper is pressed against the burrs, these burrs do not last long, so only short runs of drypoint prints are made—sometimes fewer than a dozen before the image breaks down.

If the incising is done in wood, the result is a wood engraving, as opposed to a woodcut or woodblock print, which is a relief method. Extremely hard woods can yield exceptionally fine lines, and—as with all of the intaglio methods—prints of exquisite fineness can be produced, with great subtlety in line and shade. Artists like Barry Moser have used a product called Resingrave, which is a synthetic material, mounted on a type-high block, that can be engraved in the same way one cuts into copper.

There is some confusion about the terminology here. Some people see metal engraving as an intaglio process and wood engraving as a relief process. But if the wood is engraved the same way the metal (e.g., copper plate) is, then the ink is delivered to the paper from beneath the surface of the woodblock; hence, this is an intaglio method of printing.

Intaglio-printed texts have a three dimensionality caused by the pressing of the paper into the grooves of the plate. Since this is a labor-intensive, and hence expensive, method of printing, it is highly prized. In the twentieth century a cheaper method of raised printing was invented: thermography. In this process, a newly printed sheet, with the ink still wet, is passed under a part of the press that drops a powder onto the ink. The powder sticks to the ink and the rest of the powder is vacuumed off. The sheet then is exposed to heat, which sets the powder, now raised above the sheet, creating a three-dimensional printed image. It looks from the printed surface like engraving, but from the back of the sheet one can see that the paper has not been pressed into the grooves of a printing plate.^[7] Since engraved printing is expensive and looks elegant, it was a sign of wealth and affluence to have engraved such things as business cards, wedding invitations, and stationery. Thermography imparted such a look and cost a fraction of the cost of engraving.

Advances in etching have to do with the use of lute-makers' varnish or acid-resistant resin rather than wax, the use of steel plates rather than copper, the incorporation of photography, and so forth. But the basic method of printing is nonetheless intaglio.

PLANOGRAPHIC PRINTING

In 1796 a Bavarian actor, Alois Senefelder (1771–1834), looking for an inexpensive way of printing music, invented lithography, printing from the flat surface of a stone. The invention was more of a discovery, for he was apparently not actively looking for the method that he came up with.^[8]

The basic principle is simple: oil and water do not mix. Senefelder was fortunate to be living where a particular kind of limestone was quarried. It had the properties of being able to hold on its surface an oil-based ink—called tusche—and being covered completely with water where the tusche was not, and holding both water and tusche with equal full coverage. The artist would draw the words and/or images onto the perfectly flat surface of the stone. Since the tusche was oil based, when the stone was covered with water, the tusche would repel the water and remain exposed to the air. But the rest of the stone would be covered with the water. Then an oil-based ink would be rolled on, adhering to the tusche, but being repelled by the water, hence not adhering to any other part of the stone. The paper or other material to be printed would be laid over the stone and rolled in a press similar to an etching or engraving press, and the ink would be transferred to the printing surface of the stone to the printed surface. The printing surface was absolutely flat, not in relief or in intaglio, as in the other two methods of printing described here. Hence it is called “planographic printing,” having been done from a flat plane.

The tusche is drawn onto the stone with crayons or fine pens, and under the hands of a master artist, pictures of great beauty and fineness can be created. Also, written text could be created, simply by having the lithographer write or “print out” the text in writing. Since the tusche “lies chiefly on the surface of the stone it is liable to be rubbed off, and therefore a coating which will resist any application of water is applied to it.”^[9]

The stone can be reused once the printer is finished with its image: it is reground, removing the fine layer of tusche and rendering the stone clear. The thick stones, hence, can be used over and over. By the middle of the nineteenth century the stones were printed on steam presses, speeding up the process considerably from the old method of handprinting. The thick stones are quite heavy, so a method of planographic printing was developed using zinc plates. This method was called zincography. “In 1834, the Frenchman Breugnot patented a zincographic printing process, producing large maps called géoramas.”^[10] (For this information, Wikipedia cites the dissertation of Pearson.^[11])

In 1818 Senefelder himself wrote about printing in color using lithography,^[12] and by the 1830s, chromolithography was being used in much of Europe. Chromolithographs (or “chromos”) sometimes had a dozen or more colors built up to produce the final pictures. The products from the presses often combine printing processes: usually chromos are printed first, followed by letterpress (i.e., relief) printing and/or intaglio (i.e., engraved) printing.

[More modern printing techniques are not covered in this entry. They include offset printing, rotary-press printing, flexography, screen printing, dye-sublimation printing, photocopying (Xerography), laser printing, dot matrix printing, thermal printing, inkjet printing, digital printing, and three-dimensional printing.]

Hospital Libraries

Rosalind K. Lett

Information-2-Knowledge, Atlanta, Georgia, U.S.A.

Abstract

Hospital libraries, defined as specialized professional health sciences libraries, located in hospitals, medical centers, acute care facilities, and even long term care facilities, provide biomedical information and clinical evidence-based resources to healthcare professionals, and affiliated hospital staff. In addition, many hospital libraries provide consumer health information services to patients, their families and the community. Clinical resources, particularly those focused on patient care and patient safety, differentiate hospital libraries and distinguish them from academic medical center libraries.

INTRODUCTION

Hospital libraries, defined as specialized professional health sciences libraries, located in hospitals, medical centers, acute care facilities, and even some long term care facilities, provide biomedical information and clinical evidence-based resources to healthcare professionals, and affiliated hospital staff. In addition, some hospital libraries provide consumer health information services to patients, their families and the community. Clinical resources, particularly those focused on patient care and patient safety, differentiate hospital libraries and distinguish them from academic medical center libraries. Academic medical libraries generally provide research, medical education, and clinical information to faculty, students and staff of the academic medical institution. The hospital library staff conscientiously responds to day-to-day information needs yet is always ready to handle clinical information emergencies. Hospital libraries satisfy the individual and collective needs for knowledge-based and evidence-based health information of physicians, nurses, lab technicians, students, hospital administrators, and many others. The physical library space meets multiple needs serving as a place for study, scholarly enrichment, collaborative meetings, consultations, discussions, debates, and solitude. The hospital library offers a peaceful refuge for physicians and medical school students, as well as an activity center for scholarly research and hospital-wide operational and strategic collaborations.^[1] Many other factors such as the clinical demands of the clientele, specialized print-based medical resources, electronic clinical resources, and emphasis on point-of-care patient centered information services set the hospital library apart from other medical libraries. Hospitals, especially community hospitals usually employ minimal staff for the library, often only staffing, a one-person library. Minimal square footage, limited budgets, and small resource collections are often characteristics associated with community hospital libraries. Yet even

in these less than optimum conditions a special commitment to the environment of care is demonstrated through the vision, expertise, and dedication to service of hospital librarians.

This encyclopedia entry on hospital libraries is designed to promote a deeper understanding of the:

- Value and role,
- Programs, services and information products
- Clientele and community access, and
- Changes and adaptation being made by hospital libraries

The impact of new healthcare policies, changes in the healthcare environment, new development in educational standards and evidence-based medicine, new and innovative technologies, and developing trends and patterns in hospital librarianship will serve as the basis for discussion of the above stated criteria.

HISTORICAL OVERVIEW

The hospital library of today has roots extending back to Colonial America. Dr. John Fothergill presented the Pennsylvania Hospital with its first book *An Experimental History of Materia Medica* by William Lewis, which served as the catalyst for the allocation of fund and the establishment of a Medical Library. Many hospital libraries originated from medical staff libraries, whereas others evolved from nursing libraries that supported hospital-based nurse diploma programs.^[2] The earliest medical libraries were often the results of pooled physician resources. The oldest medical library in America, established in Pennsylvania Hospital in Philadelphia, was founded in 1762. In 1847 the American Medical Association designated it as the first, largest and most important medical library in the United States. Many early hospital library collections were supported by student admission fees to

clinical lectures, bequest, gift and purchases. Through the help of Benjamin Franklin,^[3-5] John Winthrop founded a collection for the New York Hospital that was transferred in later years to form the New York Academy of Medicine. The 1800s ushered in the establishment of several notable medical libraries: the Treadwell Library of Massachusetts General Hospital in 1847, Mt. Sinai Hospital Library in 1883,^[6] and the largest hospital library at Johns Hopkins Hospital.

MISSION OF THE HOSPITAL LIBRARY

Hospital libraries, also known in some hospitals as medical libraries or health sciences libraries, are an integral part of the health care environment, which provides essential evidence-based information services.^[7] Hospital libraries, much like the hospitals and medical centers that they occupy, vary in size, scope of service, subject focus, access to resources, character and clientele.^[8] Some hospital libraries operate as independent departments, whereas others are subunits of departments, such as hospital education medical records, the medical staff office, or even quality improvement. Others are blended departments such as the Medical Library and Continuing Medical Education. The hospital's mission, vision, areas of specialty, educational offerings, participation in research and the needs of its clientele dictate the services and functions of the hospital library. Timely needs assessments and frequent usage evaluations conducted by hospital librarians provide the evidence librarians need to support the sustainability of current programs and the development of new programs and services. As hospitals add new services and expand to form multicampus systems, hospital libraries continue to develop library services to complement, strengthen and support the information needs of distance learners and the evolving needs of on-site and off-site health care providers.

In the American Hospital Association's publication, *Hospital Statistics*, hospital libraries were found to comprise the largest group of Health Sciences Libraries.^[9,10] According to statistics compiled from the National Library of Medicine's Docline records, hospital libraries in the United States currently total 3355. Today's hospital library is a uniquely specialized, patient-focused, service-oriented hub of continuous activity.^[11] Much like other departments and units of the hospital, the library contributes to the primary mission of providing service excellence and quality health care to the hospital's patients. The hospital library supports the delivery of patient care by providing library services to various types of students and health care professionals, including physicians, nurses, allied health professionals, and hospital administrators. Depending on the setting, some hospital libraries also serve nonaffiliated health professionals, such as pharmaceutical representative, and the community at large,

represented by patients and their families. The hospital library provides health care professionals with access to information used in their day-to-day clinical practice and answers to difficult health information questions.^[12] Hospital libraries also provide consumer health information and layman-oriented resources for patients, families, and the community.

Hospital libraries are the source of vital patient care information, resources to enhance education, and knowledge-based information resources needed for research endeavors. Knowledge-based information is vital to the hospital, in that it supports patient care; strategic decision making; performance improvement, patient safety, lifelong learning and reflective practice, research initiatives, patient and family education, and professional competency of hospital and medical staff. Lessons traditionally taught by hospital librarians, such as how to cite references, how to use indices, and how to develop search strategies are now being accompanied by lessons on how to search electronic resources, and how to seamlessly access health information on the web. Study shows hospital libraries save lives; ammunition in the fight to reinstate required medical libraries, the survey shows library information was often the key to proper diagnosis and treatment.^[13] Hospital librarians guided by changing roles and technology, train hospital staff to develop search strategies, search electronic books, journals and databases, seamlessly access health information from their desktop and provide training in how to analyze and filter health information.^[14] Hospital libraries also play a key role in supplying the hospital's administrative staff with information critical to making ongoing data-driven decisions.

ROLE OF HOSPITAL LIBRARIES

Historically, the hospital library has been viewed as a non-revenue generating department of the hospital, which existed predominantly to provide information and library resources to the medical staff for patient care, education, or research. The increased emphasis on the value of the hospital library in clinical care, patient safety and health literacy are presenting new roles and responsibilities for hospital librarians. These new roles have contributed to the expansion of the target audience for library services to include "all" hospital staff, patients, families, and the community served by the hospital.^[15] There are numerous types of hospitals: large and small, general and specialty, teaching and nonteaching, and acute and long-term facilities. Larger hospital libraries and multisystem hospital libraries often have more staff, larger budgets, and more resources available than smaller hospital libraries. Teaching hospitals benefit from the abundant access to monetary and physical resources particularly electronic resources of the affiliated Academic Medical Center. The library serves as a vital component in the clinical training of future

physicians, and it also serves the work-oriented need of all hospital personnel.^[16] In community hospitals, physicians and other health care professionals are made aware of the unlimited resources that the library can provide through networking with other libraries, usage of health resources on the World Wide Web and participating in consortia resource purchases and collaborative ventures.

The role of hospital libraries continues to change and evolve as information is recognized as a corporate asset.^[17] Evidence-based medicine, medical information filtering, patient safety and JCAHO requirements all focus on the quality of information and its value to the field of medicine. Providing accessibility of up-to-date, accurate, and authoritative information while the primary role of hospital libraries is not the only role. The role of the hospital library is to be agile and flexible enough to rapidly respond within the changing environment of the hospital and to provide accessibility to information for crucial data-driven decision making. However, with more emphasis on return on investment hospital libraries struggle to define themselves in such a way that the true value of intangible library services can be recognized and valued.

TYPES OF HOSPITAL LIBRARIES

Community Hospital Library

Many small community hospital libraries are designed as core medical libraries that make optimal use of limited resources. They offer a basic core collection of medical journals and texts that cover the major areas of medical practice, such as Family Medicine, Internal Medicine, Surgery, Obstetrics and Gynecology, Radiology, Public Health and Emergency Medicine. Hospital libraries provide free access to Web-based resources such as the National Library of Medicine's (NLM) Databases; PubMed, MedlinePlus, and several other Web-based NLM resources. Due to dramatic changes in access facilitated by journal publisher with input from hospital librarians, even small libraries have access to some electronic journals with the purchase of print journals. Local, regional, and national consortia affiliations help facilitate access for small libraries to electronic books, journals, and databases from recognized medical resource vendors.

Doody's Core Titles for the selection of books for the core print collection has replaced the Brandon Hill List of Books and Journals for the Small Medical Library as the resource tool of choice used to develop medical library collections.^[18] These resource collections tools are logically arranged using the National Libraries of Medicine's, NLM Classification Scheme.^[19] The smaller hospital libraries, like their larger counterparts, provide invaluable library services that include document delivery, online searching, and access to Web-based resources. The librarians in these

libraries serve as facilitators, guides, information providers, expert searchers, and negotiators.^[20] Most smaller community hospital libraries have access to the Internet, either dial-up through an Internet provider or more commonly now, through the institution-wide direct Internet connection.^[21]

Teaching Hospital Library

According to the Association of American Medical Colleges (AAMC) teaching hospitals are providers of primary care and routine patient services, as well as centers for experimental, innovative, and technically sophisticated services.^[22] Hospital libraries in teaching hospitals are vital information centers associated with teaching programs serving the hospital's objectives of patient care, education, innovation, and research. Hospital Libraries strive to develop library services that support the AAMC curricula objectives. Studies show that work-related activities are the starting point for learning for medical residents. Subsequently their information literacy skills and knowledge base are the result of the interpretation and the level of understanding that they draw from instruction and experiences such as library skills training.^[23] Teaching hospital libraries incorporate interaction into the learning process through hands-on database training, problem-based learning, the incorporation of new technologies and medical informatics applications. These libraries not only provide the core resources of the community hospital including access to point of care resources in the electronic medical record, e-textbooks, print medical text and other clinical educational resources needed in a teaching environment, but go a step further to evaluate services, analyze collections and develop more value added services for their clientele. The services of a teaching hospital's library are expanded to include bibliographic instruction (basic searching techniques), virtual reference, clinical medical librarianship, morning report, information retrieval and the incorporation of new technologies such as PDA's, iPods, smartphones and learning e-portfolios for student centered learning and the integration of resources into the electronic medical record. Many teaching hospital libraries have even begun to use some of the new social technologies, i.e., blogs, wikis. MySpace, Facebook and others social networking tools "leveraging the connectivity of the sites and using them to form communities around library products, media or information services to really be in contact with users."^[24]

Specialty Hospital Library

Specialty hospitals include acute care hospitals with one or more area of special concentration. Specialty hospitals include specialties such as pediatrics, obstetrics and gynecology, ophthalmology, otorhinolaryngology, orthopedic,

sports medicine, diabetes treatment, spinal cord injury treatment, general and plastic surgery, and diagnostic breast care. Other types of specialty hospitals are long-term care facilities such as psychiatric, rehabilitation and Veteran's Administration hospitals. Specialty Hospital Libraries foster innovation and improvement in the specialty learning environment with increased attention on residency programs and improving faculty research and patient care outcomes. Specialty hospital libraries offer residents and attending physicians a "space" in which to make connections between clinical experience, bench research projects, and program learning objectives as set forth by their program directors and department chairs. These specialty hospital libraries have in-depth collections aligned with the mission and specialization of the hospital. The collections in these facilities are comprised of core clinical journals and text, however, the primary focus of these collections is on the area of specialization of the organization.

Nursing Library

Nursing libraries provide access and preservation of scholarly records and nursing text to nursing student and nurse educators. In the 1980s, the proportion of registered staff nurses, the patient–nurse ratio increase, and a growing demand for nurses with bachelor's and master's degrees fueled the evolution of nursing. These trends toward the requirement of a bachelor's degree for nurses and the growth of nursing literature brought about by the upgrading of academic programs of nursing schools prompted the development of nursing libraries.^[25] Nursing libraries use Doody's core titles to select nursing text as well as other selection tools to build strong nursing collections. CINAHL the Cumulated Index to Nursing and Allied Health Literature is one of the Web-based resources used to locate nursing and allied health journal articles. "In many hospitals the nursing library was formalized before the medical library."^[26] Nursing libraries today are more often found in nursing schools than hospitals; however, hospital libraries provide well-developed nursing collections within their library resources, as nurses are quite often the largest user group of hospital libraries. Nursing excellence requires access to evidence-based information resources appropriate to guide health care decisions. Many hospitals today are seeking the powerful Magnet Status, recognition by the American Nurses Credentialing Centers (ANCC) Magnet Recognition Program that support nursing excellence and enhanced nursing practice, yet is very difficult to achieve. Hospital librarians are instrumental in hospitals achieving this recognition. They contribute support to the application process in many ways yet specifically by providing evidence for care delivery models, access to high quality resources and encouraging nursing research and publication.^[27–29]

IMPACT ON CLINICAL DECISIONS

Federal legislation enacted in 1986 by the Health Care Financing Administration (HCFA) eliminated the requirement that hospitals maintain a library to be eligible for Medicare and Medicaid funding. Decisions for maintaining hospital libraries were left up to the individual hospitals. The JCAHO in the 1994 standards integrated hospital libraries into the Management of Information giving hospital libraries the opportunity to explore new roles as part of the team charged with managing the organizations information.^[26] HCFA and the JCAHO have noticeably impacted decisions about the necessity of hospital libraries. As a result of the HCFA decision, the need for developing new approaches to evaluating and determining the value of hospital library services has become more apparent. Although value studies conducted by the Special Libraries Association measured monetary and time saving, additional studies of the impact of hospital library services on patient care were needed. The Rochester study was devised with objectives "to encourage hospital libraries to develop methods of analyzing current user services in order to improve the visibility and status of the library." Health care professionals make many decisions while treating patients, which are crucial to patient care outcomes and quality of care. Using the Chicago study of the contribution of the hospital library to clinical care as a model, the Rochester group developed a questionnaire to measure the impact of information on clinical decision making. This study confirmed the Chicago study findings that information provided for physicians by hospital libraries is perceived to have significant impact on clinical decision making and helps to establish the relative value of information provided by the hospital library. The Rochester study reported the information provided by librarians saved time, contributed new knowledge, improved patient care, and saved cost for 85% of participating physicians.^[27] Hospital libraries are in need of more current validation of their value. A new version of the Rochester study is being planned to help provide hospital libraries with the evidence that they need to visibly illustrate the positive impact hospital libraries have on patient care, education, research, patient safety, and health literacy. In an American Medical Association (AMA) study of New York physicians, "information provided by the library was rated more highly by the physicians than other information sources such as diagnostic imaging, laboratory tests, and discussions with colleagues."^[28,29]

LIBRARY STANDARDS

Two important sets of standards affecting hospital libraries have been significantly revised. These are the Medical Libraries Association Hospital Libraries Standards and the Joint Commission on Accreditation of HealthCare Organizations (JCAHO) Standards.

The Medical Library Association Standards

The Medical Libraries Association (MLA) is the organization representing health sciences librarians and other health information professionals dedicated to improving their leadership and quality to foster the art and science of health information services. The Hospital Libraries section of MLA composed standards for hospital libraries that were approved in 1952. A major revision to the Hospital Library Standards was performed in 2002 with updates made in 2004. The Medical Library Association's *Standards for Hospital Libraries 2002* were developed as a guide for hospital administrators, librarians, and accrediting bodies to ensure that hospitals have the resources and services to effectively meet their needs for knowledge-based information (KBI).^[30]

JCAHO STANDARDS

The Joint Commission on Accreditation of Healthcare Organizations (JCAHO) is the major accrediting agency for hospitals. In the JCAHO standards for information management, the importance of the need for access to knowledge-based information provided by hospital libraries is outlined in the Agenda for Change. JCAHO has identified expert knowledge-based information as vital to an organization's ability to provide patient care. Knowledge-based information refers to current expert information, produced externally to the organization, including:

- Journals, texts, documents, and databases in print or electronic format;
- Benchmarks, best practices, guidelines, consensus development statements;
- Research studies;
- Quality-filtered Internet resources

According to JCAHO, knowledge-based information is a collection of stored facts, models, and information that can be used for designing and redesigning processes and for problem resolution.^[31] Knowledge-based information is found in the clinical and management literature, derived from in-house library collections and external databases. The JCAHO standards for information management focus on the accessibility, availability, and the authoritative nature of knowledge-based information included in the institution-wide planning.^[26] "Knowledge-based information supports clinical decision making, continuing education of staff, administrative planning and management, performance assessment and improvement, patient and family education, and research."^[32] JCAHO regards information management as a function composed of seven strategic processes that look at needs identification, systems design, information definition and capture, data analysis, data transformation, data transmission, data reporting, and

information assimilation and usage. The newly revised integrated JCAHO standards incorporate information management as a component of quality improvement. As part of the continuous efforts to monitor the library services within the health care environment, the JCAHO developed a new vision of information that is critical to quality care and thus integral to all JCAHO standards.

The JCAHO has changed standards affecting hospital libraries. While the standards state that access to knowledge-based information is needed for the hospital environment, they no longer definitively state that the hospital library is the place for this access. The JCAHO is currently proposing revisions to the management of information standards that could classify hospital libraries standards as nonessential standards. MLA and the hospital library community are providing valuable feedback to the JCAHO to maintain the recognition of the value and need for the hospital library.^[33-37]

LIBRARY CLIENTELE

Hospital libraries serve the entire hospital community. Research, training, and information resources are provided to physicians, nurses, allied health professionals and other hospital staff. Drug information and pharmaceutical reference materials are available for pharmacists and other clientele needed drug information. Patient education materials are provided to case managers and staff who plan patient discharge strategies. Dietary information is provided to dietitians and nutritionist. Information on the environment-of-care is provided to administration, hospital safety personnel and public safety officers. Comparative data is provided to quality improvement teams and senior administration to make critical data-driven decisions. New technological developments and innovations are provided to information systems personnel and informatics researchers. Knowledge-based, data-driven decisions are made by hospital administrators based on information obtained by the hospital library from business, statistical, technological, and hospital administrative literature resources. Hospital libraries also serve students, interns, and residents by offering bibliographic instruction, reference assistance, seamless access to print and nonprint resources, paper-based and online catalogs, dictionary, thesauri, controlled vocabularies, and standard nomenclatures.

The information explosion has made us acutely aware that medical literature is growing at an astronomical rate.^[38] The number of medical articles available on the Internet increased from zero in 1992 to 107 in 1995 to 3.8 million in 1997 and continues to grow exponentially.^[39] A quick Google search reveals 217,000,000 medical articles. Physicians find they can't keep up with the enormous volumes of biomedical information published, even when regularly reviewing current literature. The information

explosion has brought about a new age of technology for hospital libraries and a new value to hospital librarians as information experts.^[40] The hospital library also plays a major role in the service to patients and their families. Information can increase consumers' receptivity to treatment by improving their knowledge about disorders and treatment alternatives. Information also enhances the patient-clinician relationship by facilitating informed consent and fostering patients' active participation in their treatment. Some hospital librarians have gone as far as to participate in training consumers of health information to make sense of medical data by supporting literacy initiatives.^[41]

The current emphasis of the JCAHO on patient education and the rights of consumers to be informed before consenting to test, treatment, and drug therapy have led to a renewed interest in patient libraries.^[42] A resurgence of patient libraries is being seen in all types of hospital libraries. Patient and consumer library services in today's hospital provide layman's level, easy to understand information about illness and wellness for the general public. The educated e-health consumer of today seeks direction in searching the literature and locating alternative avenues of health care.

LIBRARY STAFF

Role of the Hospital Librarian

Hospital librarians function as problem solvers, change agents, and invaluable resources of timely information delivery, yet they also serve as generalist. Although generalism contributes greatly to library work, specialized skills are especially critical to developing quality collections and first rate services.^[43] As medical librarianship became more widely accepted as a profession, standards for certification were established, which have evolved into the present day Academy of Health Information Professionals (AHIP).^[44,45] The staffing of hospital libraries is uniquely different, depending on the size of the hospital, the availability of funding for library resources, and the organizational commitment to lifelong learning.

The medical librarian, a specialized information professional, is uniquely prepared to provide oversight and management of knowledge-based information (KBI) resources and services to hospital or healthcare system. The hospital librarian plays a significant role in bringing specialized competencies to the institution, for the selection, organization, dissemination, evaluation, and expert retrieval of information in support of knowledge-based and evidence-based clinical, administrative, and scientific decisions. Hospital libraries have a vested interest in training health sciences practitioners and other library clientele in the best methods of information retrieval for knowledge-based and evidence-based practice, research, and lifelong learning.

Today's hospital librarians function in the roles of library manager, information specialist, webmaster, database manager, clinical medical librarian, information analyst, chief information officer, informationist, and internal consultant. The hospital library manager works closely with hospital managers and professionals in other disciplines on a daily basis. The job of hospital library manager is accompanied to a great degree by autonomy that allows flexibility and rapid response to the ever-changing needs of the hospital staff. As information specialist, hospital librarians focus on providing expertise in the location and delivery of information resources. The role of web master taps the creative and organizational skills of hospital librarians. Designing, organizing, and maintaining a web site for the library and sometimes multiple sites for the organization, provide a different dimension to the hospital librarian's job. As database manager, hospital librarians develop, classify, and maintain databases of pertinent information, making it available for rapid retrieval. Clinical medical librarians connect with the clinical staff as a part of the clinical team to provide information at the point-of-care. In the role of chief information officer, the librarian is the architect of the organizations' strategic information plan.^[46] As internal consultants, hospital librarians cultivating entrepreneurial spirit, evaluate current processes and contribute to the development of new services such as competitive intelligence. These services are the basis of ideas that produce new income streams and incorporate significant cost savings for the organization.

Educational Requirements for Hospital Librarians

The staff of hospital libraries ranges from the one-person librarian experiencing a wide variety of work interactions, to a library staffed with three or more full-time staff members, each devoted to one or more specific aspect of library operations (i.e., document delivery and circulation). Most hospital librarians hired today to manage hospital libraries have earned a master's degree in library science from an American Libraries Association accredited library school. The master's degree provides general, multidisciplinary preparation for library work. Specialized course work in medical librarianship provides the subject concentration in medical and health sciences resources. The educational background of library staff varies from certified medical librarians with master's degrees in library science, to library specialist with undergraduate degrees in related disciplines, to library assistants with 2 or more years of college and library experience.^[47] Although having a science background is not a requirement to become a hospital or health sciences librarian, the knowledge-base of the life sciences curriculum prepares librarians for in-depth analysis, research, and filtering of biomedical information which proves invaluable in biomedical informatics. The staff of hospital libraries provide valuable database search

training, while offering service assistance in retrieval of information from Web-based resources, locating and delivering needed documents, developing resource collections, providing access to electronic resources and supplying other vital information services.^[48]

Most hospital libraries not employing a full-time certified medical librarian seek support from the services of a degreed medical librarian, either as a consultant or circuit rider librarian. Library consultants assist libraries in the day-to-day maintenance of the library and keep the library's operational policies in compliance with JCAHO standards. Library consultants provide a variety of services onsite or virtually. Circuit rider librarians usually serve a number of hospitals. They travel from library to library providing basic information services and collection maintenance for several hospital libraries, usually in rural areas.^[49] Library and information services provided by professional librarians are critical to the organization's ability to not only respond to information requests but also proactively meet the ever changing needs and systematically link current, standard evidence from the literature with health care processes.

SERVICES

The Medical Library Association sites 19 services as being essential to hospital libraries. These essential services are categorized as distinct functional areas that include Technical Services, Reference and Information Service, Educational and Outreach Services, and Administrative and Management Services.^[50,51]

TECHNICAL SERVICE

One of two major functions of libraries, technical services includes processes for acquiring, arranging, indexing, and storing the collection. The constant replenishing of selected materials and the routine update of standard library references fulfill the mission of acquisitions. The acquisitions process includes tasks that involve ordering, receiving, and paying for information resources.^[52] For most library clientele, the processing of books, journals, A-Vs, CD-ROMs, electronic resources and software is invisible. The process-oriented functions that convert collection development decisions into acquisition are the backbone of the development of a strong authoritative library collection. Many methods, such as analysis of citations and resources, library usage studies, and subject expert collection evaluation, are used to judge the value of library resources.^[53] The acquisitions staff of hospital libraries, one-person or larger, perform a variety of tasks that address many complex issues concerning licensure, contracts, discounts, and electronic format of resources.

Collection Development

The library's mission, objectives, and goals reflect those of the parent organization, as do the library's collection development policies. The information needs of the organization served by the hospital library are figured prominently into the collection development plan.^[54] Selecting materials for inclusion in the collection of a hospital library can be a complex process. The needs of library clientele, the current collection strengths and weaknesses, the demands of cooperative collection agreements, the need to preserve historically important documents, the available space, in-house and online journal use counts, and impact factors enable a balanced, objective approach when making difficult choices of how to spend limited collection development budgets.^[55,56] The scope of the collection development plan parallels the organizations commitment to various activities and disciplines. The proliferation of published materials, in all forms, is so vast that no single hospital library, not even the largest, can hope to acquire everything. Selection is necessary to ensure the viability of the collection and the incorporation of various materials in subject specialties. The underlying principle of the selection policy defines what the library should get rather than what it does get.^[57] The basic principle of selection is derived from assessing and understanding the needs and interests of the clientele and applying basic selection principles. Assessment of information use, demand, and needs of library user groups, both potential and immediate, provides a context for the library staff to make selection decisions for the library.

Medical books correlate information from many primary sources such as journal articles and present the subject in context, often revealing both past and present advances, and future trends. Medical books provide tremendous timesaving when clientele need comprehensive literature analysis, review and comparisons to find different perspective, interpretations, and outlooks.^[58] The transformation of traditional print medical books to online digital electronic books is occurring very rapidly. Online medical books are an important resource for digital library collection building, especially in the context of clinical medicine. Hospital libraries have a unique obligation to advocate for the shift from print book collections to electronic book collections. Hospital Libraries have been successful in increasing their electronic book collections by focusing on the elimination of space requirements for electronic books, the convenience of access, and the cost benefits of acquiring e-books within database packages, such as in the case of MD Consult. Consortial collaborative purchases of product such as STAT!Ref or Books@Ovid are other ways Hospital Libraries facilitate the shift to electronic books.

The hospital librarian has a responsibility to establish and maintain library liaison groups, to evaluate information trends, and to be proactive in response to changes in

health care.^[53] An important aspect of selection is learning about new publications that can enhance and strengthen the library's collection and purchasing the most appropriate format of that resource. Information is being packaged in a variety of innovative formats, yet budgetary constraints drive hospital libraries to develop more rigorous selection methodologies and to redefine the criteria and processes by which decisions are made to insure accessibility to resources and efficient allocation and use of funds.

Circulation

A major function of the hospital library is to provide conditions for optimal, seamless use of library resources by clientele both inside and outside of the library. Development of circulation policies and procedures for hospital libraries begins with the identification of the population to be served. The policies governing the use of the library by the clientele reflect and enhance the vision and mission of the hospital. Establishing use policies in hospitals often involves collaboration between the librarian(s), the library committee, and hospital administration. The library circulation policies reflect a wide range of library clientele with varying and unique needs.^[59] Circulation of print resources has been significantly impacted by the introduction and proliferation of electronic resources, yet many high use titles are maintained in both electronic and print format.

Access to the Library Collection

Information is viewed as a basic commodity in the health care field. Access to up-to-date, authoritative information is critical to the success of a hospital library in serving the needs of its clientele. The library collection is comprised of its information sources (i.e., journals, e-journals, books, e-books, audiovisuals, databases, practice guidelines, patient education materials and Web-based resources. Many hospital libraries, historically, have limited access to physicians, because of the limitations of spaces and staff, and the technical level of the library resources.^[60] Today's access to the hospital library collection is provided to all hospital staff and the community during normal business hours. After hours access is provided for clinical staff and hospital administrators, which give them 24-hr access to the resources of the library. The availability of books and journals in electronic Web-based formats provide opportunities for desktop access to library resources virtually 24 hrs a day. Desktop access to online catalogs, bibliographic databases, full-text journals, electronic reserves, and virtual reference services has visibly changed library use patterns. These new formats provide searching, filtering, analytical and access capabilities that aid in rapid location and critical appraisal of information. Libraries are experiencing decreases of in-house use of

library resources, with patrons opting to use the convenience of online full-text resources made freely available from the hospital library. The provision of resources in the myriad of formats currently available support the "equal access to health information resources" called for in MLA's WHCLIS platform.^[61]

Access to Bibliographic Information

Two types of documents (indexes and abstracts) contain catalogs and bibliographies of original materials, primarily articles in periodicals. The National Library of Medicine created Index Medicus, a finding aid for biomedical journal articles. Index Medicus was produced as a monthly listing of current articles and cumulated yearly into the Cumulated Index Medicus. Index Medicus is the paper index whose entries dating back to 1966 comprised the MEDLINE database.^[62] Most indexes and abstracts used by hospital libraries are currently available electronically. The "List of Serials Indexed for Online Users" (LSIOU), listing 5164 journal titles, provides bibliographic information for all journals ever indexed over time for MEDLINE®. It includes titles that ceased publication, changed titles, or those that were deselected.^[63,64] CINAHL, the Cumulative Index to Nursing and Allied Health Literature was originally a print index to the literature of nursing and eventually allied health information. The CINAHL® database has emerged as a comprehensive, authoritative and versatile guide to current periodical literature for nurses, allied health professionals and to an exploding body of health related knowledge, which now extends beyond the limits of a bibliographic print index. Approximately 2900 nursing, allied health, and health related journals are regularly reviewed and indexed for inclusion. Full text articles are available for selected nursing standards, practice acts, pamphlets, state nursing journals, research instruments, and critical paths.^[65]

For subject areas not highly demanded, hospital libraries obtain journal article information by searching other indices and databases. For subject areas in high demand, libraries purchase a site license to the Web-based content, access databases through resources purchased in consortia packages, call upon colleagues at academic medical center for help, or use resources of statewide library resource sharing project such as Georgia's GALILEO. GALILEO, or Georgia Library LEarning Online, is a world wide Web-based virtual library, providing access to multiple information resources, including secured access to licensed products. GALILEO provides access to over 100 databases indexing thousands of periodicals and scholarly journals, 2000 full-text journal titles and other resources including encyclopedias, business directories, and government publications available primarily to citizens of Georgia.^[66] Many states have similar resources that hospital libraries tap to locate needed resources. One major

advantage of electronic indexes and abstracts is the feature that enables clientele to search for information using words from titles and abstracts in addition to the author and subject access provided in print versions. This significantly expands the number of information paths available to locate bibliographic information.

Library catalogs are used in the circulation and location of library resources. The early systems still used by only a few hospital libraries are catalog card dependent. This type of card catalog facilitates location of library materials though access to cards organized by subject, title, and author. Hospital libraries now use computerized integrated library systems (OPAC) Online Public Access Catalogs, which record information about both the user and the circulating materials. The OPAC records are created from the library's electronic bibliographic records. The records are accessible through searching software. OPACs can be a part of an integrated system or self-contained packages, as they are in many hospital libraries.^[63] The online catalog provides menu-driven searching of book, journals, and audiovisual databases by author, subject, title, format, and keyword. These catalogs provide features such as browsing by title, limiting searches by date, access from remote terminals and other specialized features.

EDUCATIONAL SERVICES

End-User Training in Database Searching

Bibliographic instruction (BI) of medical literature searching in the hospital setting focuses on teaching effective use of appropriate health information resources. Many hospital librarians provide BI to new and seasoned employees, residents, nursing students, house staff, and liaison groups of the hospital. Topics traditionally taught include accessing and organizing information, using library locator tools, citation verification, computerized bibliographic database use, searching electronic journals, utilizing interlibrary loan services, and using Medical Subject Headings (MeSH).^[67] Internet searches for information constitute one of the most popular applications taught in BI. Training of end user (library clientele) to search in-house databases, Web-based resources and electronic full text journals are high-profile services common in hospital libraries. Alper and Visnon conclude in a study at the University of Missouri, that introducing students to useful Web sites, practicing answering clinical questions, and integrating this process with clinical rotation experiences can reduce the effort that students need to find answers and improve the quality of answers they find.^[68]

The introduction of end user searching systems beginning in the late 1980s initiated a wave of change at the traditional reference desk as users began to discover new ways to utilize library services. With the introduction of end user MEDLINE in the 1980s, many hospital libraries

found an increase in requests for individualized instruction, technical assistance, and in-depth reference assistance. With the availability of new information resources, library users find reference services helpful in helping them adapt to newly emerging information landscapes. Enabling end-user access has contributed to a decline in traditional reference services such as mediated searching yet has stimulated the development of new roles of hospital librarians performing more comprehensive subject focused expert searching, filtering, and critically appraising literature.^[69] Critical appraisal is the study of two main elements of research; how the research was performed and how the research and findings are presented. When hospital librarians critically appraising a study they are attempting to reduce the uncertainty, focus on important issues, dissect complex problems and corral group participation. Critical appraisal is an essential step in evidence-based decision making. The decision to implement change can be made more accurately after conducting a critical appraisal.^[70]

The need to assess the quality of end-user training has drawn attention to the need to evaluate both search ability and the ability to use the resulting information to accomplish a clinical task. End-user searching is usually conducted using electronic bibliographic databases such as PubMed and CINAHL. These databases allow searching by keyword and retrieval of references list. The end user must then sort, read, and critically evaluate the results to uncover answers and results for patients. New third generation evidence-based medicine search engines allow access to hundreds of the best known therapy options through clinical knowledge management systems. These systems use simple "ask a question" interfaces to retrieve the latest peer reviewed research. Results are synthesized into article summaries, tables and graphs with links to original articles. Hospital librarians teach end users to search these databases focusing on their ability to synthesize large bodies of information, and the expanded modules available. Up-to-Date, Dynamed, Cochrane, Google Scholar, Pubmed, and Medical Evidence Matters are valuable resources for obtaining new evidence-based medicine information.^[71]

REFERENCE AND INFORMATION SERVICES

Reference and Information Services are the services that range from provision of quick answers to simple questions, to providing in-depth research to answer complex questions. The challenge of reference services is providing precisely what the client needs, in the allotted time, and format.^[72] Day-to-day reference work in a hospital library follows a pattern influenced by the nature of the requests for services. Hospital librarians conduct reference interviews, the process of asking open-ended questions, to clarify the client's request, in-person, via telephone, and even virtually. Request for information takes several forms: factual or "direct" inquiries, bibliographic or "indirect" inquiries, and

verification request. Factual inquiries include statistics, biographies, locations, a historical data, a formula, a definition, or some similar fact. Five filters are used by librarians to translate request into searchable questions. They include defining or qualifying the subject, establishing the need for the information, pinpointing personal traits of the requester, exploring the relationship of the inquiry to the organization, and determining acceptable answers.^[73] The rise in electronic document access has revolutionized rapid delivery of health sciences information, making desktop access to and electronic delivery of health sciences information the preferred method.

Reference

The reference process consists of three primary elements: information, the user, and the librarian.^[74] Hospital libraries house a myriad of sources, which prove to be useful for answering factual questions. Virtually every book and journal in the collection is a potential information source. However, dictionaries, directories, catalogs, handbooks, encyclopedia, or similar publications are typically referred to as reference resources because of their format. The user or client is the person posing the question, who generally is unsure of what information they need or the best method of locating needed information.

The role of librarians in the current problem-based hospital environment is to provide the knowledge that facilitates expert performance. The hospital librarian interprets the reference question, evaluates available resources, and identifies the exact resource to supply the answer.^[9] Reference services can be broadly divided into three functional areas: 1) information retrieval; 2) information access; and 3) information management. Performing reference services, librarians have traditionally given personal assistance to clientele making the best use of collections to satisfy their information needs. Librarians use their skills and acquired techniques to access, sort, transfer, evaluate, filter, and disseminate information.^[75] The publication of printed catalogs and bibliographies, the accessibility of online catalogs and multimedia databases, along with the organizing of the national interlibrary loan system (DOCLINE) have widened the range of resources available to the individual library client.^[76] As a result, librarians are increasingly called on to help clientele determine the most efficient tools to use in their research. In hospital libraries, assistance includes explaining the layout of the library, the process of locating material, and the availability of services. Also, providing guidance about information on subject-specific medical resources is a popular service. This process is greatly expanded by the enormous increases in research worldwide, the virtual explosion of Web-based electronic resources, and the quantity of language formats available for media and publications.

Virtual reference, the delivery of personalized information resources to users physically outside of the library, is

a sophisticated use of Web-based technology, yet only being explored and contemplated in the majority of hospital libraries.^[77] The potential benefits of using a virtual reference chat service to answer remote patron questions has not been convincingly conveyed to hospital librarians. Providing key services through the Internet has challenged hospital libraries to embrace the library without walls philosophy. It has become increasingly important to reach those people who don't come to the library to request library services. Chat services offering personal and immediate connections provide a place to connect with users and non-library users offering them both convenience and information service. Questions directed to virtual reference services ideally are ready reference questions that can be answered quickly. Complex labor intensive reference questions are often answered via e-mail following the chat session, if additional resources are needed. Many questions can be answered satisfactorily using features such as co-browsing or page pushing that facilitate librarians demonstrating use of electronic resources. Firewall issues and Hospital Information Technology department restrictions block many hospital libraries from using popular free chat based utilities like AOL instant messenger, MSN messenger, Yahoo! Messenger, Google Talk, or Trillian. Commercial services such as Docutek, Tutor.com, Live Chat and QuestionPoint are expensive and often out of reach for hospital libraries. Hospital libraries are finding ways to work cooperatively with Information Technology to uncover the benefit of the free virtual reference environment.^[77]

Information Services

The subject search is one of the areas on which advancing technology has had the greatest impact. The transformation from timed fee-based database searching, to CD-ROM access, to free Web-based access to MEDLINE has provided hospital librarians the opportunity to search more thoroughly and use specialized features to create a variety of enhanced services. In many hospital libraries, a variety of computer-based information retrieval systems provide access to materials on- and off-site. For example, one development in subject access increases the amount of information that is available within library catalogs by including details from the table of contents, a book's index or keywords. Other systems provide enhanced features that include full-text articles, and links to related articles. "These full-text references eliminate intermediate steps characteristic of older systems requiring users to first perform an electronic search and then obtain the articles themselves in print."^[78]

MEDLINE

The availability of electronic resources has made a dramatic impact on today's health care professionals' access

to information. The need for information services in a hospital setting has rapidly changed as the virtual library emerges. A trend equally important is the ongoing role hospital librarians play in creating, strengthening, reshaping, and transforming hospital libraries into integrated knowledge management centers.^[63]

The literature search is one of the primary services of hospital libraries. MEDLINE, the National Library of Medicine's database of references provide access to more than 16 million articles published in 5000 biomedical journals. The subject scope of MEDLINE is biomedicine and health, broadly defined to encompass those areas of the life sciences, behavioral sciences, chemical sciences, and bioengineering needed by health professionals and others engaged in basic research and clinical care, public health, health policy development, or related educational activities. MEDLINE also covers life sciences vital to biomedical practitioners, researchers, and educators, including aspects of biology, environmental science, marine biology, plant and animal science as well as biophysics and chemistry.^[79] Many of the listings also have short summaries of the article (abstracts) and quite often a link to the complete article (full-text) through BioMed Central or a link to the journal. Most of the articles found in MEDLINE are written for health professionals and thus are complex and not easily understood by layman.^[80]

In 1997, the National Library of Medicine opened up MEDLINE (the world's largest database of medical literature) to the public on the Internet free of charge. PubMed is the National Library of Medicine's search service that provides access to MEDLINE, PreMEDLINE, and other related databases, with links to participating on-line journals. Access to medical information is provided by a number of aggregators supporting access to several biomedical databases and electronic journals using one common search protocol. Aggregators such as OVID, EBSCO, Thomson, Elsevier, and McGraw Hill producing such products as MD Consult, Up-to-Date, DynaMed, STAT! Ref, and many other products are commonly used in larger hospital libraries and those affiliated with teaching hospitals, whereas smaller hospital libraries depend primarily on free access to PubMed and its related biomedical resources.^[9]

Current Awareness Services

Hospital libraries provide current awareness services sometimes called SDI's (Selective Dissemination of Information or Alert Services). These services set up literature searches on specific topics that are run automatically to provide current updated information. Patrons are alerted periodically via e-mail, receiving URLs to web pages of automatically generated updates to their selected topic and of new journal issues, and new publications pertinent to their field. This type of service can increase a user's ability to keep current and may have a positive

impact on efficiency and productivity.^[81] Some hospital libraries use (TOC) or Table of Content Services as a means of promoting review of current article titles. The TOC allows library clientele to view online contents pages of journals selected from the hospital's list of serials. These services are ideal for keeping patrons up-to-date on their areas of interest.^[82] For those hospital libraries unable to subscribe to fee-based TOC services, free alerting service such as Pubcrawler, BioMail and Jade whose scans are updated daily to PubMed databases and provides individuals with listings of new database entries that match their research interests.^[83] Other less expensive alternative methods such as scanning of tables of content pages and locally distributing them to enables libraries to increase access to journals and, more importantly, provides a viable alternative to routing and potentially losing journals. Some small hospital libraries still use routing of new journals from office to office as their method of increasing clientele awareness of recent journal literature.

Interlibrary Loan and Document Delivery

Interlibrary loan (ILL) is the process of borrowing and lending books, audiovisuals, and journal issues to other libraries for use by library clientele. Interlibrary loan is a long-time cooperative effort among all types of libraries, as are serials union list and cooperative cataloging projects on the Internet, such as EPIC/OCLC (Online Computer Library Center) and RLIN (Research Libraries Information Network).^[84] Document delivery is the process of delivering journal articles or photocopies of needed documents. Hospital libraries use DOCLINE, a comprehensive routing system of the National Library of Medicine to facilitate reciprocal borrowing and lending of library materials from hospitals and major medical libraries around the world. Hospital libraries routinely use DOCLINE as their primary electronic network for requesting loans and lending resources.^[85] More than 57,000 libraries in 112 countries and territories around the world use the Online Computer Library Center (OCLC) services to locate, acquire, catalog, lend and preserve library materials. Hospital libraries use OCLC to locate nonmedical documents, reports, proceedings, and other nontraditional resources.^[86] Larger hospital libraries sometimes purchase software that allows them to manage their resource sharing activities. OCLC's ILLiad Resource Sharing Management Software helps libraries automate routine interlibrary loan functions, which increases productivity and dramatically reduces paperwork.^[87] All of the library's borrowing, lending and document delivery activities are managed through a single Windows-based interface, which allows library patrons to submit and track their own requests via the Web. Prospero, an open access Document Delivery System is available free of charge to libraries seeking low cost resources management software.^[88]

Outsourcing

An alternative to in-house initiation of document delivery, cataloging and other library services used by some hospital libraries is the contracting of library services to independent information professionals, information brokers and consultants. Hospital libraries use independent information professionals or consultants when patron expectation of rapid delivery increases and more comprehensive document delivery services are needed. When budgetary constraints prevent hospital libraries from supplying needed materials, library clientele are sometimes referred directly to independent information professionals or consultants often affiliated with the Association of Independent Information Professionals (AIIP).^[89] The Association of Independent Information Professional members are owners of firms providing such information-related services as online and manual research, document delivery, database design, library support, consulting, writing, publishing, library space planning, website design strategic planning and overall information architecture.^[90]

Online Access to Other Library Collections

For years, libraries shared information about the resources held in library collection through union catalogs available on microfiche or in print using the consortium approach. Access to Web-based union catalogs has enhanced the hospital libraries access to library resources owned by other libraries. These catalogs have been redesigned and have evolved to Web-based products, such as WorldCat, OCLC's union catalog. WorldCat is the world's largest collaboratively-produced network of library services built upon a massive database of bibliographic, ownership and other forms of metadata. The core WorldCat database contains the merged catalogs of thousands of OCLC member libraries and is collectively maintained by those members' information professionals. WorldCat includes over 88 million bibliographic records and serves more than 57,000 participating libraries worldwide.^[91] Hospital librarians search the computerized catalog holding of libraries around the world to locate needed resources. The National Libraries of Medicine offers hospital libraries an invaluable resource for locating hard to find materials, foreign journal titles, and obscure publications.^[92,93] Hospital libraries use NLM's online catalog, LocatorPlus (<http://locatorplus.gov>) to find biomedical articles held by academic medical centers, hospitals, and other health care agencies. LocatorPlus is continuously updated and includes: over 1.2 million catalog records for books, audiovisuals, journals, computer files, and other materials in the Library's collections. Holdings information for journals and other materials, links from catalog records to Internet resources, including online journals and circulation status information for materials, even those on-order or in-process at NLM can be found in LocatorPlus.^[94]

ADMINISTRATIVE AND MANAGEMENT

The hospital library manager will spend much time in the future developing analytical skills to look more at what can be rather than at what presently is the state of hospital libraries. Steven O'Connor notes that a change in thinking must occur, suggesting that library managers must understand not only what business the hospital library is in but what business it should or could be in.^[95] The use of new cutting edge technologies, more stringent legal requirements, heightened standards of accountability and outcomes driven services have dramatically impacted the management of services, staffing, and physical facilities of hospital libraries. Hospital library managers are responsible for budgeting and personnel management, as well as developing policies for acquisitions, planning, marketing, fundraising and service evaluation. Hospital library managers analyze customer satisfaction data to restructure priorities, functions, and supporting services of the library. Keeping up with the enormous amount of information available, forging new methods for 24/7 access to up-to-date biomedical resources, and mapping out unique approaches to outreach are only a fraction of the managerial decisions that hospital librarians face each day. Like managers of other hospital departments, hospital library managers use tried and true participatory and shared models of management to engage employees in the day-to-day operations of the library. In addition to making organizational information decisions, hospital library managers review policies and procedures, comply with internal organizational mandates and create, implement and sustain a vision of service for the hospital library. Hospital library manager must face the hard cold fact that perception of service bears far greater importance than reality. These managers exhibiting intelligence, creativity, and leadership must be willing to leave their comfort zone and begin to mold and shape the perception of reality of their clientele.

Fiscal Management

A mission statement quickly and concisely identifies the role of the one-person or multiperson library, connects it to the parent organizations' mission, and describes briefly what the library does. As part of their administrative duties, hospital managers develop skills in preparing, presenting, and negotiating appropriate budgets. Collective concortial purchasing, creative fund-raising, and project-specific grant writing are alternative means of acquiring needed funds for operational, personnel, and capital expenditures. The hospital funding environment, particularly for technology purchases has become very competitive. Many hospital libraries must prepare business cases and cost savings analysis that illustrate the return-on-investment expected to justifying expenditure of large technology purchases. The National Networks of

Libraries of Medicine and the Institute for Museums and Libraries Services are but a few of the national organizations that offer to large and small hospital libraries, funding options through grants proposal solicitation.

Human Resources

Hospital library managers are responsible for the recruitment, hiring, evaluation, professional development, and ultimately the retention of staff in the hospital library. It is not uncommon to have a library staff range from .5fte to 5fte. Regardless of staff size, staff development is important to personnel enrichment. In today's hospital setting, library team dynamics are extremely important. Librarians serve on teams with their library colleagues, as well as with colleagues from other hospital departments and other hospital affiliates. Working in a library presents unique service-oriented situations, as a vast percentage of your requests come from unscheduled encounters, walk in, phone in or e-mail request. This creates special time management challenges, whereas in most other professional environments clients are meticulously scheduled.^[96] Balancing the management of time, setting goals and priorities and appropriately delegating responsibilities are proven strategic skill sets that hospital librarians and hospital library managers must fully embrace. In the fast paced clinical environment where scheduled agendas can quickly be erased by the need for clinical information to deal with a medical emergency, it is imperative that hospital librarians master the art of providing just in time, right on time health information.

Marketing

Marketing perpetuates the hospital library focus on customer-centered approaches to promoting health and wellness. Hospital librarians continuously reevaluate services and target markets to assess the true value of library services. Establishing library advocates among library users and supporters to champion library causes is a strategically insightful way of avoiding budget cuts and staff downsizing. The Internet and newly created social technologies have presented fresh approaches to reaching target markets. Using resources like Blogs, Wikis, Podcast and unlikely sources for advertising like Facebook or Utube hospital libraries can provide the visibility that the library needs to attract new patrons and meet the new generation of users where they connect. For many hospital libraries word-of-mouth marketing has worked for years, however, as hospital systems grow and expand, more and more hospital libraries develop more formalized marketing efforts. National Medical Librarians month in October and National Library Week in April are great times to devote to marketing of current and new services for the library. New marketing techniques such as merchandising can be useful to hospital libraries in drawing attention to

their consumer health information collection.^[97] The fundamental function of merchandising is to encourage the customer to discover and select more than they anticipated. Strategically placed, book features prominently displayed and other powerful illustration play a crucial role in steering customer traffic. Merchandising does the job of maximizing turnover of popular categories or drawing attention to under-utilized parts of the collection. The overall objective is to create interest and prompt impulse loans.^[98]

Planning

The rapid pace of change and the transformation from traditional library roles to new roles supporting advanced technology and electronic environments requires library staff to routinely conduct service audits and environmental scans. Strategic planning and scenario planning are critical component of an efficient, cost effective hospital library operation plan. To stay agile and responsive to client needs hospital libraries need to examine their services, processes, and structure.^[99] Using the mission and vision of the hospital the hospital librarian examines the environment to develop an environmental scan, conducts a SWOT analysis, and map out goals supported by measurable SMART objectives. Developing a staff strategic plan for 3–5 years is recommend, although the library staff should review the strategic plan often to make sure that their services, collection development, educational programs, and capital expenditure are aligned with the stated goals.

Space planning supports the library's strategic direction, creating a reality of collaborations and virtual service. The hospital library manager charged with the task of planning renovations and new construction of hospital libraries space seeks to blend high tech and high touch services. Using vision, knowledge of operations, functional process analysis, and flexibility, library managers can assist architects in designing space that is both aesthetically pleasing and functionally sound. The current trend in libraries is to devote a significant portion of the space to computers and collaborative meeting space.^[100] Electronic resources have reduced some of the needs for collection space but surplus workspace in hospitals is always at a premium and rarely available.

As demands for hospital resources increase, hospital library managers face competition for limited resources, and therefore, must continuously cultivate their management skills and fiscal resources to be competitive and effective. The future hospital library manager will need to have a more global outlook, applying more flexible and creating more options for developing plans for the hospital library.

Assessment

The Medical Library Association Standards 6 for medical librarians recommends that librarians provide evidence of

an ongoing assessment of the knowledge-based information needs of the organization and best practice.^[101,102] The hospital librarian is charged with developing and implementing a plan to provide appropriate resources, services, and technology to meet those identified needs. Library decision makers can more accurately evaluate the quality of current library services, and appropriately allocate scarce resources when assessments of library performance are properly designed.^[103]

Using many adapted variations of formal and informal tools, techniques and methodologies hospital librarians assess the knowledge-based information needs of the hospital or health care organization. Assessments that incorporate, opinions and feedback from library users and nonusers can play a significant role in directing the library's strategic path.^[104] Some of the more popular techniques used include focus groups, surveys, usage patterns analysis, environmental scans, strategic planning, inventory, budgetary planning, and one-on-one interactions with health care leaders focusing on clinical and organizational information needs.

ORGANIZATIONAL CONTRIBUTIONS

Access to the Internet

Staff access to Internet services is available in most hospital libraries; however, public access to the Internet may not be as accessible, depending on the size of the library, the availability of computer workstations, and type of Internet connections available. When the computer to user ratio changes from "one to one" to "many to one" a significant change in how people relate to health information can be expected. Libraries use the Internet to access resources in response to reference questions, for searches on specific data, providing public access to customers, participating in listserv or discussion groups, and relaying resources electronically to their customer.^[74] Constructing home pages for World Wide Web access has become a vital activity in hospital libraries. Library staff participates in defining policies and setting guidelines, designing user-friendly interfaces, and producing easy access to all inclusive electronic information resources. Community hospitals in rural and isolated areas have traditionally lacked the infrastructure for institution-wide access to the Internet, so dial-up access is used as a low-cost, low-risk means of access to the Internet for the hospital library. Using the Internet to connect community hospitals with major research centers is particularly important especially in areas sparsely populated and where large distances separate facilities.^[74] Advances in telecommunication and information technologies have been the foundation of connectivity for small and community hospitals.^[105] Hospital libraries that directly access the Internet are connected through the organizations' computer network. As with so many other

initiative in community hospitals cost remains a major barrier to establishing direct connections to the Internet. The National Libraries of Medicine recognizes the role of information in the provision of care and have developed, through the Regional Medical Libraries, Library Improvement Project Grants and Express Welcome Grants to assist community hospitals in getting equipment and Internet Service Providers to connected to the Internet.^[106]

Hospital librarians play a central role in introducing the Internet to clinical settings. Trends show a rapid increase in the Internet's importance as a source of medical information. The Internet has the potential to empower patients and to bring evidence into medical practice, but also to facilitate reference questions, instruction and seamless access to endless health sciences resources. External information resources continue to be more affordable and more readily available to hospital libraries of all sizes. These external resources help create a network of virtual resources that expands the collection of even the smallest hospital library. To meet the information needs of health professionals, many librarians are using the Internet to access NLM databases and other specialized databases for document transmission, search training tutorials, extend library hours with after hours access, connect directly to NLM publications and other resources, and participate in professional discussion groups and electronic mail.^[107] The vast amount of current information on the Internet and the relative ease with which it can be searched make it today's best medium for health research.

Customized Services

Hospital librarians are information experts who can decipher the vast body of information available in print and nonprint resources. Along with providing information on what is available additionally they customize search strategies that help locate the exact information needed. As an accepted organizational information experts hospital librarians participate on internal committees, special task force, new project initiative and as vital members of the information management team.

As educational programs and the need for continuing education expand, hospital libraries provide medical students, residents, health care providers and hospital staff with resources for participation in distance learning, technology application, social networking connections and system-wide collaborations. Likewise they provide opportunities to access continuing education programs using cutting-edge technologies, such as podcasting, webinars, video streaming, web casting, and using other digitally formatted media.

Services for Decision Makers

Hospital administrators play a vital role, managing hospitals, outpatient clinics, hospices, long-term care facilities

and drug-abuse treatment centers. The hospital administrator's primary job is to make sure the hospital operates efficiently and provide optimal medical care to patients. Their abundant responsibilities sometimes require the assistance of support staff such as hospital librarians. Administrators focus on expanding existing programs and services and developing new ones for preventive medicine and systematic research, in research oriented hospital. Administrators in teaching hospitals focus on pursuits necessary to educate future doctors. They plan and monitor departmental activities, evaluate health care professionals, create and update policies, develop medical treatment standards, continuously improve quality patient care services, and proactively participate in fund-raising and community health planning.^[108] Hospital administrators must keep up with innovations and advances in the medical and health care environment, computer and information technology, diagnostic and therapeutic equipment, government regulations, health insurance industry trends, and financial options. Hospital libraries provide the comprehensive, reliable information.^[108] Hospital administrators need to make critical decisions about the myriad relevant health issues and the exponential changes and challenges in health care. The hospital library serves the administrative and health care needs of the administrators, supplying them with the tool needed to compare cost, review trends, assess feasibility and analyze return-on-investment. The foundation for administrators' priority setting criteria are interwoven in the mission of hospital libraries. Hospital library services support the organizations' strategic direction, supplies research for government regulation compliance, reinforces education and research through scholarly resource access, provides clinical evidence to insure clinical competence, and partners with patients and communities encouraging coordination, collaboration and seamless access to health information resources.^[109] Business resources such as *Business Week*, and the *Harvard Business Review*, in addition to newspapers, news wires and other business related databases are frequently searched and filtered by hospital librarians, to retrieve data, statistics, trends, regulations, standards, and data-driven information that impacts hospital policies and procedures. While doctors strive to keep the pulse regulated and the heart beating, the hospital administrators keep the hospital alive and vibrant with the expert assistance of hospital librarians who keep them well-informed and data-driven.

Clinical Medical Librarianship

Clinical medical librarians (CML) provide special services to teaching hospitals by participating in medical staff rounds with assigned clinical teams noting clinical questions as they arise. Clinical medical librarian services allow hospital librarians to be highly visible and integrated into research, teaching, and clinical services.^[110] The presence of the clinical medical librarian in the hospital

corridors often inspires clinicians to remember questions they had forgotten to pursue with the library. The clinical medical librarian is seen as a valuable team member in health care education and delivery. When clinical cases are presented, and discussed the clinical medical librarian is able to recognize and respond to information needs that are never formally voiced or directly requested. The clinical medical librarian sees medical problem solving and decision making take place in the actions and the informal, abbreviated language of the health care practitioner. This gives the clinical medical librarian an opportunity to learn how knowledge-based information is used and to understand clinicians' requests more clearly.^[111] The future of clinical librarianship is deeply rooted in health sciences informatics and the Informationist. Health Sciences informatics has been defined as science that deals with the structure, acquisition, and use of health related information. Florance defines an informationist as one who is "cross-trained in medicine, computer science and information science."^[112] The role of the Informationist is to clearly understand the principles of clinical work and information science. The ultimate responsibility is to enable clinicians to apply better judgment based on improved use of medical literature.^[109] Davidoff estimates that of the 6500 U.S. acute care hospitals, only about 200 have implemented clinical librarianship programs due to the lack of financial incentives. Several funding ideas have surfaced such as, inclusion of cost in telemedicine grants and demonstrating information value to improved outcomes and cost reduction to the Health Care Finance Administration to justify reimbursement.^[112]

Health Literacy

Physician-patient communication is vital to patients complying with physician instruction; however, research shows that patients have problems understanding medical instructions from physicians. The use of medical jargon, the lack of confirmation that patients understand instructions, and the delivery of too much information at one time contribute to low health literacy. At the end of the medical encounter, patients remember less than half of what the physician tried to explain, and they may be uncertain about what steps to take next.^[113]

Thirty million Americans are below basic literacy levels and are unable to perform literacy task above simple, basic interactions, according to the 2003 National Assessment of Adult Literacy. Another 63 million are only able to read and understand short, everyday text, placing them at the Basic literacy level.^[114] Health Literacy is defined simply as the ability to read, write, and understand health information. Increasing attention has been given to the provision of health information to patients, families, caregivers, and the public. The American Hospital Association (AHA) has stated that health education is an integral part of high-quality patient care and has issued a Patient's Bill of

Rights, expressing patient's rights to obtain understandable information concerning diagnosis, treatment, prognosis, and support documentation for informed consent.^[115] Hospital libraries have been increasingly engaged in exhibiting their capabilities to provide easy to read, understandable information to patients. At the same time, new consumer health information services have been incorporated in hospital libraries, aiming to combine the subject expertise of the hospital library with the accessibility of the public library. The amount of published literature on health topics for lay people has expanded exponentially. The shift to consumer health information has been encouraged by government health policies that emphasize consumer's right to choose. In 1991, the Patient's Charter, which emphasizes patient's rights to receive health care on the basis of clinical need, regardless of their ability to pay, was launched by the government. More importantly for libraries, the charter guarantees patients the right to be given clear explanations of any treatment proposed, including risks or alternatives, before they decide on treatment.^[116] The Center for Clear Health Communication provides many tools to help libraries and health educators select easy to read materials and create health care documents using minimal jargon and simple easy to follow instructions.

Many contemporary patients expect to be educated about their medical conditions and treatment options. In response to these expectations, hospital libraries provide consumer health information written in layman terms to patients and their families. Books, magazines, videos, and computer-based resources are available to answer questions dealing with patient health concerns. The Medical Library Association has defined the role of the medical librarian in the provision of consumer health information. Their responsibilities are to determine the most prevalent diseases and to identify the most authoritative resources pertaining to these diseases.^[117]

Hospital librarians often use the National Library of Medicine's (NLM) MedlinePlus database, <http://www.medlineplus.gov> to locate easy to read patient education materials, drug information, and interactive tutorials. MedlinePlus provides access to MEDLINE and numerous other helpful tools, including a medical encyclopedia, several medical dictionaries, a drug reference guide, and general health information. MedlinePlus also includes detailed reports on the diagnosis, prognosis, and treatment of numerous medical conditions, along with links to hundreds of reputable health organizations.^[118] Hundreds of consumer health and layman-oriented web sites are currently available on the World Wide Web; however, the absence of authority of much of the information is a formidable problem. Different methods of quality control are being proposed for information on the Internet. One promising approach is automatic downstream filtering, the process of software (browser) checking of metadata-labeled information to determine if the information meets the personal quality requirement of the searcher. Metadata

describes the content and context of the information, thus allowing the user to determine suitability of the information for individual use.^[119] Hospital librarian also provide guidance on evaluating health information Web-site for accuracy and quality.

In recent years, there has been a growing body of research producing evidence on the positive effects of the provision of information to patients. These positive effects are noted as improved patient satisfaction, reductions in pain, fewer postoperative complications, shorter hospital stays, reduction in blood pressure, and improved self-management of conditions such as diabetes and kidney disease.^[120] In 1991, a consensus statement was issued "underlining the effect of information giving." Two key areas were identified as benefits of giving health information: reduction of anxiety in patients and families and increased compliance with medical instruction given by care providers.^[121] The power of information to produce a more informed, thus more compliant patient population is becoming evident. The provision of information to patients is equated to raising expectations, challenging professional mystiques and outdated ideas, sharing decision making, and most importantly, sharing power. All health care consumers need access to a wide variety of unbiased health information resources, regardless of their age, sex, educational level, socioeconomic status, or ethnicity.^[122]

CONTRIBUTIONS TO OTHER HEALTH CARE ORGANIZATIONS

Participation in Cooperative Networks

"The focus of library cooperation is the network. The network is defined as, a group of individuals or organizations that are interconnected to form a system to accomplish some specific goal." Hospital librarians serve as knowledgeable guides through the maze of resources and as liaisons to networks with other libraries for resource sharing.^[123] Hospital libraries participate in cooperative networks with the National Library of Medicine, other hospitals, and academic health science libraries to expand their base of available resources. Hospital libraries band together to form consortia that provide enrichment opportunities for hospital librarians, maximize purchasing power, and address community health needs. Hospital library consortia support law librarians and their thirst for medical information, public librarians, in their quest for medical information retrieval skills, and other special libraries seeking comparative medical information for benchmarking, innovative research and scholarly enrichment.

Loansome Doc

Library staff are extremely service-oriented, providing access not only to all categories of staff at the parent

institution but frequently also to community health professionals not affiliated with the institution and to patients and their families. Many hospital libraries participate in the National Library of Medicine's program of supplying medical documents to health professionals not affiliated with their parent institution. Recent surveys show that usage of Loansome Doc is low. Additionally, the major barriers to use are cost and timeliness of the service.^[124] Greater promotion of what Loansome Doc is and how it can benefit libraries can increase the number of participating libraries. While satisfaction of Loansome Doc end users is high, satisfaction could be increased with more help on the PubMed screen, more library training, and faster delivery methods.^[125]

Loansome Doc is a service that allows nonaffiliated groups or individuals to set up an agreement to have a specified hospital library serve as their "home" library for retrieval of articles and library resources that they need. Independent unaffiliated physicians, attorneys, pharmaceutical companies, and other health care organization representatives search MEDLINE and then request photocopies of articles of interest via Loansome Doc. Copies are provided from the home library collection or requested by using the DOCLINE network.^[126] These services are generally provided on a cost-recovery basis.

Hospital libraries advocate for access to authoritative up-to-date health information for all affiliated users. Hospital librarians provide an environment that discourages the digital divide by providing libraries with computers for access to technology and fostering an open attitude of cooperation.

FUTURE CHALLENGES

In the information age, sensitivity to the stresses of change affect information utilities like libraries as much as they do other organizations. In a time characterized by layoff, downsizing, rightsizing, restructuring and reengineering, the ability to look forward reflectively, and plan for significant transformation in health care is a huge challenge to all types of libraries, but especially hospital libraries. Future challenges for hospital libraries and the librarians that staff them will center on finding solutions to budgetary constraints, significant changes in user demands, and effects of massive technological changes. The continued need to reach out globally beyond physical walls, firewalls and country boundaries drives the vision of the global virtual library. Heighten pressure will engulf hospital libraries forcing them to continuously demonstrate their contribution to better health care outcomes through the provision of point-of-care access to information resources and services. The visual illustration of the hospital libraries' positive impact on the bottom line of the organization will also be a point of concern. Hospital libraries continue to be challenged to demonstrate their value through

research, outreach, making multiple resources available to patrons onsite and offsite, and revising data gathering. Concentrated effort will also be centered on improvement of dissemination operations, analyzing and evaluating self-help information access, mapping information activities to outcome measures analysis, and visibly supporting innovative problem-based learning, and evidence-based medicine practice.

Electronic Resources

Desktop access to online catalogs, bibliographic databases, and full-text journals is changing library use patterns.^[127] Hospital libraries' shift from ownership of physical collections to licensing content for electronic resources has occurred quickly in support of medicine and science, despite budgetary limitations.^[128] Changes in the practice of medicine and technological developments offer hospital librarians unprecedented opportunities to select and organize electronic resources, use the web to deliver content throughout the organization, and improve knowledge at the point-of-need. Due to the vast array of available electronic products, access protocol, and pricing structures hospital librarians are faced with anticipating the electronic resource needs of users, identifying leading resources, making sound budgetary decisions, efficiently managing the collection, and seamlessly organizing health information resources. The electronic resource marketplace requires much vigilance, considerable patience, and continuous evaluation. Hospital librarians employ several strategies to proactively stay ahead of the electronic resource curve, including accepting and marketing free trials from publishers; conducting user-based new product evaluation; monitoring and testing products directly marketed to clientele; beta testing new products and services; working with aggregators or re-publishers; joining vendor advisory boards; benchmarking institutional resources against competitors; and forming or joining a consortium for group negotiating and purchasing.^[129] Access to electronic books and journals in large and small hospital libraries is due in part to publishers providing limited free access to electronic journals when print copies are purchased, and greatly attributed to shifts in physician's demands for easy to access information resources onsite and offsite. Hospital libraries continue to struggle with journal issues such as access vs. ownership. Constantly faced with electronic access issues ranging from content, licenses, cost, interfaces, technical presentation, and management of electronic journals, hospital librarians are called upon to develop new strategies for building the library's collection and integrate digital resources. Recent trends in hospital libraries shows evidence of a growing shift toward totally digital libraries in hospital settings.^[130]

Electronic document delivery systems are setting the stage for exploitation of image technology and providing

more global access to full-text digital images. The development of document delivery enhancement products, such as ILLiad and Prospero, to assist in the efficient management of document delivery processes have helped hospital librarians reduce turnaround time on delivered health care documents, improve customer service and better manage their electronic resource.^[131] The quality standards of electronically delivered documents continues to improve as PDF (Portable Document Format) formatting of electronic documents is adopted nearly universally as the format of choice.^[132] Hospital librarians join their academic counterparts to advocate for the adoption of HTML (Hypertext Markup Language), SGML (Standard Generalized Markup Language) and Open eBook, XML-based formats as the new standards for electronic content.^[133]

Training in the use of electronic resources is extremely important in the hospital library. Not only are hospital librarians responsible for acquiring and organizing electronic content but they must assess the best ways to train hospital personnel in the effective location, access method and utilization of electronic resources.

Social Networking Technologies

Witnessing a rapid increase in the use of Web-based “collaborationware” in recent years has made hospital librarians begin to seek ways to implement this technology in the hospital library. Web 2.0 applications, particularly wikis, blogs, and podcasts, have been increasingly adopted by many health sciences libraries. This “collaborationware” offers the opportunity for powerful information sharing and ease of collaboration. Their ease of use and ability for rapid deployment make them desirable particularly for hospital libraries however, often hospital system firewalls prevent their implementation.^[134]

Wikis are Web sites that can be edited by anyone who has access to them. The word “blog” is a contraction of “Web Log”—an online Web journal that can offer a resource rich multimedia environment. Podcasts are repositories of audio and video materials that can be “pushed” to subscribers, even without user intervention. These audio and video files can be downloaded to portable media players that can be taken anywhere, providing the potential for “anytime, anywhere” learning experiences (mobile learning). Wikis, blogs, and podcasts are all relatively easy to use, which partly accounts for their proliferation. The fact that there are many free and Open Source versions of these tools may also be responsible for their explosive growth. Web 2.0 sociable technologies and social software are presented as enablers in health care environments.^[135] The most prevalent social networking technology includes: social networking services, collaborative filtering, social bookmarking, folksonomies, social search engines, file sharing and tagging, mashups, instant messaging, and online multiplayer games. The more popular Web 2.0 applications in education, namely wikis,

blogs, and podcasts, are but the tip of the social software iceberg. Web 2.0 technologies represent a quite revolutionary way of managing and repurposing/remixing online information and knowledge repositories, including clinical and research information.^[136]

As internal organization Information Technology departments loosen their restrictions on the use of social technologies in the hospital environment, hospital libraries will be challenged to incorporate these “collaborationware” technologies to more seamlessly connect, and collaborate with library patrons. The new social technologies combined with innovations with instructional technology create new digital learning environments for educating hospital staff in the use and location of digital resources. Research centered on information-retrieving patterns of clinicians and other focused groups will become more important in the design of libraries and the introduction of new services. As hospital libraries grapple with staffing issues, they will see an increased need for development of instructional interactive video media for provision of more seamless library tours, orientations, and bibliographic instruction.^[137]

Evidence-Based Librarianship

The evidence-based movement has changed in response to health care; as a result, evidence-based healthcare has evolved with greater flexibility and adaptability for disciplines outside clinical medicine. Evidence-based librarianship (EBL) incorporates the decision-making framework, the basic process, and many similar research methods apparent in evidence-based medicine yet its’ flexibility and adaptability are characteristics of evidence based health care.^[138] The conceptual framework of evidence-based librarianship seeks to improve library practice using a combination of librarian experience and best evidence. It encourages the application of best evidence and the pursuit of increasingly rigorous research strategies. Hospital librarians are incorporating evidence based librarianship as they convert clinical information needs into answerable questions, tracking down and critically reviewing the best possible evidence, estimating benefits, judging value and ultimately developing clinical practice guidelines to efficiently guide future similar decisions.^[139] The EBL process enables hospital librarians to focus on a specific problem in need of immediate attention thus integrating research findings into their daily practice.

The EBL process consists of formulating a practical question, searching for the evidence needed to answer the question, and systematically evaluating the gathered evidence for its usefulness and validity for answering the initial question.^[138]

Health care professionals suffer from information overload and struggle to filter evidence relevant to their

field. Hospital librarians provide filtering and delivery of information specifically tailored to meet the needs of researchers and practitioners. One special need filled by hospital librarians is the production of systemic reviews. The systematic review process is the concept of evidence-based medicine (EBM), which Sackett defines as “the conscientious, explicit and judicious use of current evidence in making decisions about the care of individual patients.”^[140] One way hospital librarians provide support for EBM is by using the Cochrane method of conducting systematic reviews of the literature. The hospital librarian’s training as an expert searcher, organizer, and analyzer uniquely quality them to conduct systematic reviews.^[141]

Educational Role in Outreach

Hospital librarians are defining new expanded roles for supporting the educational needs of the hospital. As they do this they present a variety of opportunities to bring professional expertise to ongoing assessment and the development of best practice. New technologies provide new forums including using online instructional technology like Moodle to provide Web-based training.

Disparities in health between minority and majority populations have become a topic of high interest in the health care and information communities. Hospital librarians are aggressively embracing their role in working with physicians to develop solutions to issues addressing health disparities, patient safety, and environmental justice.^[142] They design and implement personal digital assistants (PDA) programs to assist physicians in getting information at the point-of-care, and institute clinical librarianship programs allowing them to make clinical rounds with physicians, thus impacting decisions from the question’s origin.

Hospital librarians play a significant role in reaching out to teach information access skill but also in teaching courses on information filtering, evidence-based medicine, interactive learning techniques, critical appraisal, editing and refereeing of online journal articles, and the construction of specialized knowledge bases to other health professionals in the community.^[143] Teaching hands-on information retrieval instruction enhanced by computer-assisted instruction programs to facilitate problem-based learning skills and simulations for decision processes and strategies will strengthen patient-centered librarianship and solidify the role of hospital librarians as evidence educators. Hospital librarians will be challenged to search more complex information, analyzing and synthesizing results into packaged reviews while interacting with their clientele primarily by using electronic mail, blogs, wikis, electronic teaching platforms, podcasts, and other electronically linked networks.^[144,145]

Digital Resources

As more hospitals merge into integrated health care systems, hospital librarians are challenged to function as

outreach consultants, serving the needs of staff at off-site facilities. The rapid growth of scanning and digitizing technologies has provided new methods for retrieval and delivery of print documents, pictures, graphs, charts, and full text to off-site hospital staff. Portable Document Format (PDF) is the standard format for delivering full text of electronic journal and book resources.

The shift to wireless computer access, flat-screen technology, iPods and other Mp3 players, eBooks, sharper image handheld devices (as easy to read as paper), are presenting unique planning challenges for all health sciences libraries. Recent developments in computer technology have introduced us to the optical mouse, wireless networking, USB ports, jump drives, fiber optic and video transmission systems, for distance education, webinars for teleconferencing. Desktop computer applications have become more adaptable and interface with more customizable technology. Cellular telephone devices such as the iPhone now integrating telephones, iPod, Internet, cameras, blue tooth, and other technologies provide consumers with endless communication options.^[146] Voice over Internet Providers (VoIP) are providing access to telephone service through internet connections. Given these innovative options hospital librarians focus on finding ways to integrate these new technologies to enhance seamless delivery of information solutions. The future for hospital libraries holds possibilities of teledesk located throughout the hospital allowing interactive visual and voice connections. Hospital libraries are faced with designing facilities and reallocating space to support wired and wireless technology while building platforms to integrate innovative connectivity and point-of-care information access.

In addition to the changes in the methods of information delivery, new forms of information that include “hypertext, cd and digital video interactives, expert systems, knowledge bases and virtual reality” show significant promise in providing a new qualitative approach to information delivery.

Value Added Service

“Value-added” is a marketing concept that expands or modified a product or service so that it has added value to the customer. For example, offering a MEDLINE search may be a basic service provided by the library; a value-added MEDLINE search is one where, the librarian has analyzed the search, selected several of the most relevant articles, and included full-text copies of these articles in a complete package.^[147,148] Hospital librarians may even filter the articles included to provide a summary of the pertinent points outlined in the articles. Quality filtering is a service usually performed on research studies or clinical trial articles. It involves identifying the hypothesis of the study and extracting vital information from the article to give clinicians a clear picture of the type of research study conducted and the validity of the results.^[149]

Hospital libraries continually seek to develop and promote value-added services to ensure customer satisfaction and quality service. One of the significant challenges for hospital librarians continues to be the use of knowledge-based information resources and new technologies to create Web portals for the provision of easy access to resources tailored to suit the institutions' unique needs. License agreements and institutional restrictions often limit patron access depending on their affiliation with the hospital.

Occurrence screening is a service that provides the opportunity for librarians to independently analyze raw quality improvement data to determine the overall need for information. Information provided through information screenings is distinctive in that it isn't a response to a specific case presented in the morning report; rather, occurrence screening educational packages address best practice patterns or state-of-the-art methods of patient care to anticipate and diminish future clinical problems.^[150]

Communicating the role of information in the provision of care continues to challenge hospital librarians. However, as Quality Oversight Organizations (QOO) encourage community hospitals to embrace the concept of integrated information management for the improvement of quality, hospital librarians have begun to realize opportunities to incorporate Internet usage as a clinically indispensable tool.^[151]

Knowledge Management

Knowledge is defined by Peter Drucker as "Information that changes something or somebody—either by becoming grounds for actions or by making an individual (or an institution) capable of different or more effective action."^[152] Knowledge Management (KM) is a platform for implementing organizational change; by getting people to record knowledge (as opposed to data) and then share it. In short, it is a way of channeling raw data, into meaningful information.

The concepts of knowledge management is providing a new dimension in library service, as the collection and preservation of explicit (informal) internal knowledge is further explored and meshed with the application and use of tacit (formal) knowledge. KM is linked to what people know, and how what they know can support the organizational objectives. Based on assumptions of strategic planning, the time value of information, and cross-functional teams, KM deals with the most meaningful, practical, and purposeful ideas. KM is ever changing, value added, and visionary. The constant revision and updates of knowledge illustrate the importance of viewing KM as an ongoing process that draws upon pooled expertise, relationships, and alliances. The role of the hospital library in KM is to introduce the concept, provide knowledge expertise and generate enthusiasm, buy-in, and motivation, encouraging managers to work together toward reaching common knowledge preservation goals.^[153]

Hospital Librarians will be challenged to share their expertise in categorization and segregation of knowledge to create and update working databases and digital libraries, allowing more efficient access to specific, recent, relevant information through keyword or subject searching. Hospital librarians can also provide more information support through participation in research teams that use information-based techniques such as meta-analysis to blend integral digital and traditions knowledge.^[154]

Electronic Health Record and Electronic LATCH

The merging of information technology and health care has contributed to the shifting of attitudes from health care provider to consumer and facilitated the creation of the Electronic Health Record (EHR). The patient centered electronic health record is designed as a cross-institutional, longitudinal information record aimed at establishing a record that contains all consumer health information from "the cradle to the grave."^[155] Hospital libraries have the opportunity to challenge conventional thinking about the (EHR) to offer Literature Attached to Chart (LATCH) programs to expand the library's patient care support and compliment other health information. LATCH programs will enable health care personnel to request and review, up-to-date disease specific articles attached directly to the electronic medical record as URLs, PDF or scanned document. Librarians will be able to document evidence to support clinical decisions, thus potentially contributing to reduction in medical errors and cost. LATCH programs will also provide documentation of physician's verbal request for literature to support a diagnosis or treatment, thus providing supporting documentation to help resolve legal disputes.^[156]

Good communication between patients, providers and librarians is an essential component of high-quality patient centered health care. Communication between patients and providers has traditionally occurred through in-person, telephone, or paper-based encounters. Due to the evolution of technology patients and providers are enabled to communicate electronically to obtain follow-up test results, collect information before a visit, schedule appointments, send reminders, ask questions, renew prescriptions and in the near future to request health information for addition to their electronic medical record.^[157] The EHR offers great potential for hospital librarians to develop and evaluate access protocol, research information seeking behaviors, manage personalized health information web page development and facilitate usage of digital resources.

Consumer Health Trends

One of the highest priorities in today's hospital is the provision of quality care to patients. Consumer health information services make important contributions to

consumer choice, safety, literacy, and quality health care. They indicate the need to set up networks for shared development of quality standards and training. Consumer health databases in all formats and the extension of services into new areas that examine quality of care and effectiveness of treatment are warranted. Attention needs to be focused on developing networks to maintain current awareness and creating more standards for best practice.^[158] Hospital librarians will be challenged to assist consumers and hospital staff in checking the authenticity and integrity of Internet sites and providing consumers with a higher level of decision-enabling information. A congressional report published in 1988 points to new emphasis on scientific reviews of the outcome and effectiveness of treatment.

The report states that providing information to consumers on quality of care enables people to avoid poor quality providers and educates the public on the concept of quality. It also injects competition into the medical marketplace and stimulates clinicians to improve practice.^[159]

For this to take place, hospital libraries must begin to support consumers with a more focused level of information. Information should be provided on the mortality rates of hospitals and the adverse effects of treatment, including nosocomial (hospital acquired) infections. Disciplinary actions against doctors and patient satisfaction results should be readily available to help individuals make informed personal choices.^[160] Evidence-based Librarianship seeks to provide replicable standards for information retrieval and dissemination. The challenge of information providers is to find a way to translate this technical information into digestible information that patients and their families can understand and use to make more informed health care decisions. The creation of the individual health record is an excellent start. This record will allow patients to track their medical care in all aspects of care. This record is a logical place to have literature searches about conditions and disorders recorded to assist the physician in providing optimal care and monitoring the literature as it related to your health conditions.^[161]

CONCLUSION

"Clearly, for hospital libraries to survive, their existence must be validated and their contributions must be shown to be consistent with the overall goals of the hospitals they serve."^[162] The future of hospital libraries depend on their ability to promulgate new images of hospital librarian's work that convey professionalism, documented value and quality. Hospital libraries are transforming into hubs of electronically based research, where hospital librarians provide practical, workable solutions to the information

challenges of the constantly changing world of evidence-based health care. Balancing information resource formats, cutting edge technologies, patient safety concerns, innovative social networks of communication, and an environment centered on Evidence Based Health Care will continue to create unique challenges for hospital libraries.^[163] As hospital libraries continue to reengineer themselves, define new roles, focus on resource access and service excellence, the intangible and tangible value of health care information at-the-point of care will become more apparent. Hospital libraries and librarians must take the lead in proactively identifying and adopting new and changing responsibilities. Hospital librarians must take the lead in developing essential evaluative measures, ideas, energy, and relationships through out the hospital to promote and market the vision, mission and value of the hospital library. As Garfield states, "unless the hospital library becomes fully recognized as a legitimate part of the medical facility, cost-conscious administrators will use outdated models of library service to cut library budgets."^[164]

Hospital libraries will serve as the gateway to the application of new creative ways to use internal wikis, comment-enabled internal blogs and other collaborative tools. Hospital libraries will more thoroughly explore the applications of web 2.0 technology, such as creating internal podcast lab to enable users to generate podcast, and creating user generated content tagging, making content easier to locate.^[165] Hospital Libraries will be challenged to help create new knowledge tools, using such as organization-specific mashups, to integrate internal information with open source content, creating new discovery tools.^[166]
